Pearson, 2020

# Transport layer: overview

*Our goal:*

- understand principles behind transport layer services:
  - multiplexing, demultiplexing
  - reliable data transfer
  - flow control
  - congestion control
- learn about Internet transport layer protocols:
  - UDP: connectionless transport
  - TCP: connection-oriented reliable transport
  - TCP congestion control

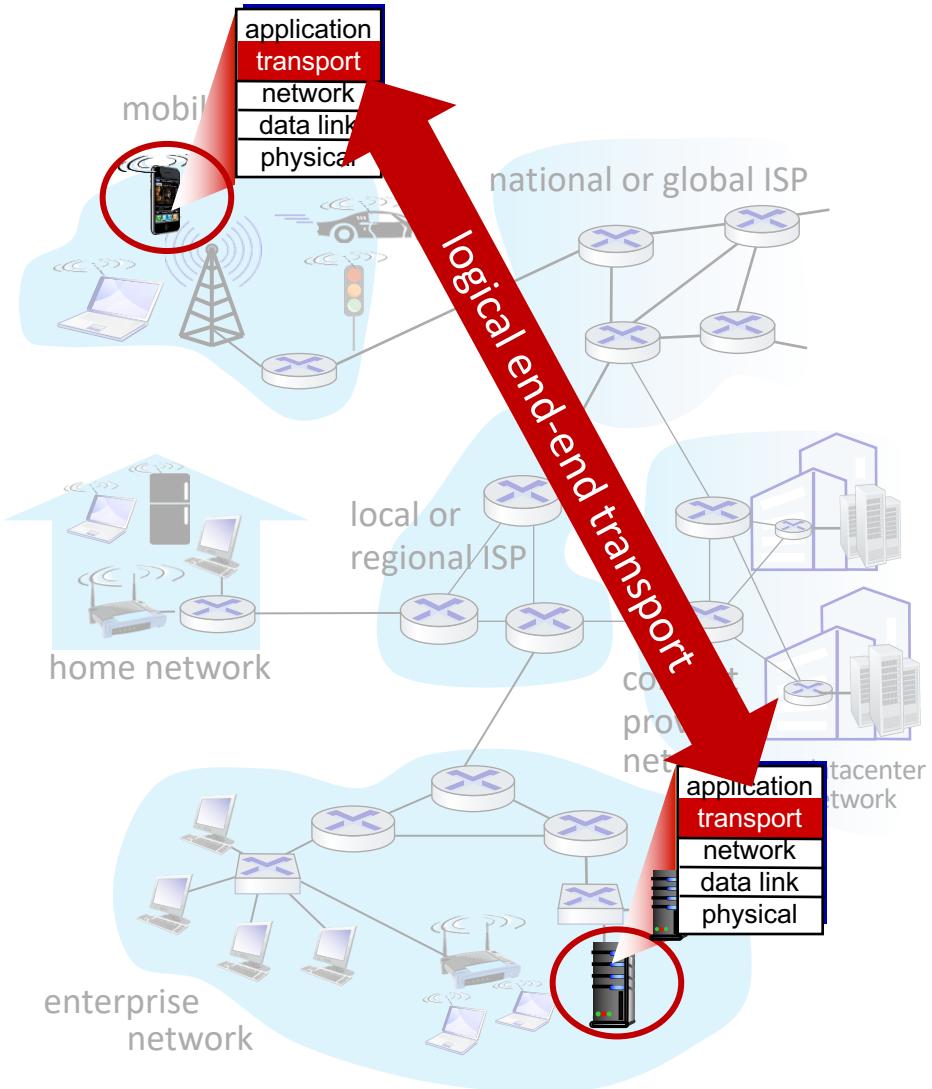

# Transport layer: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

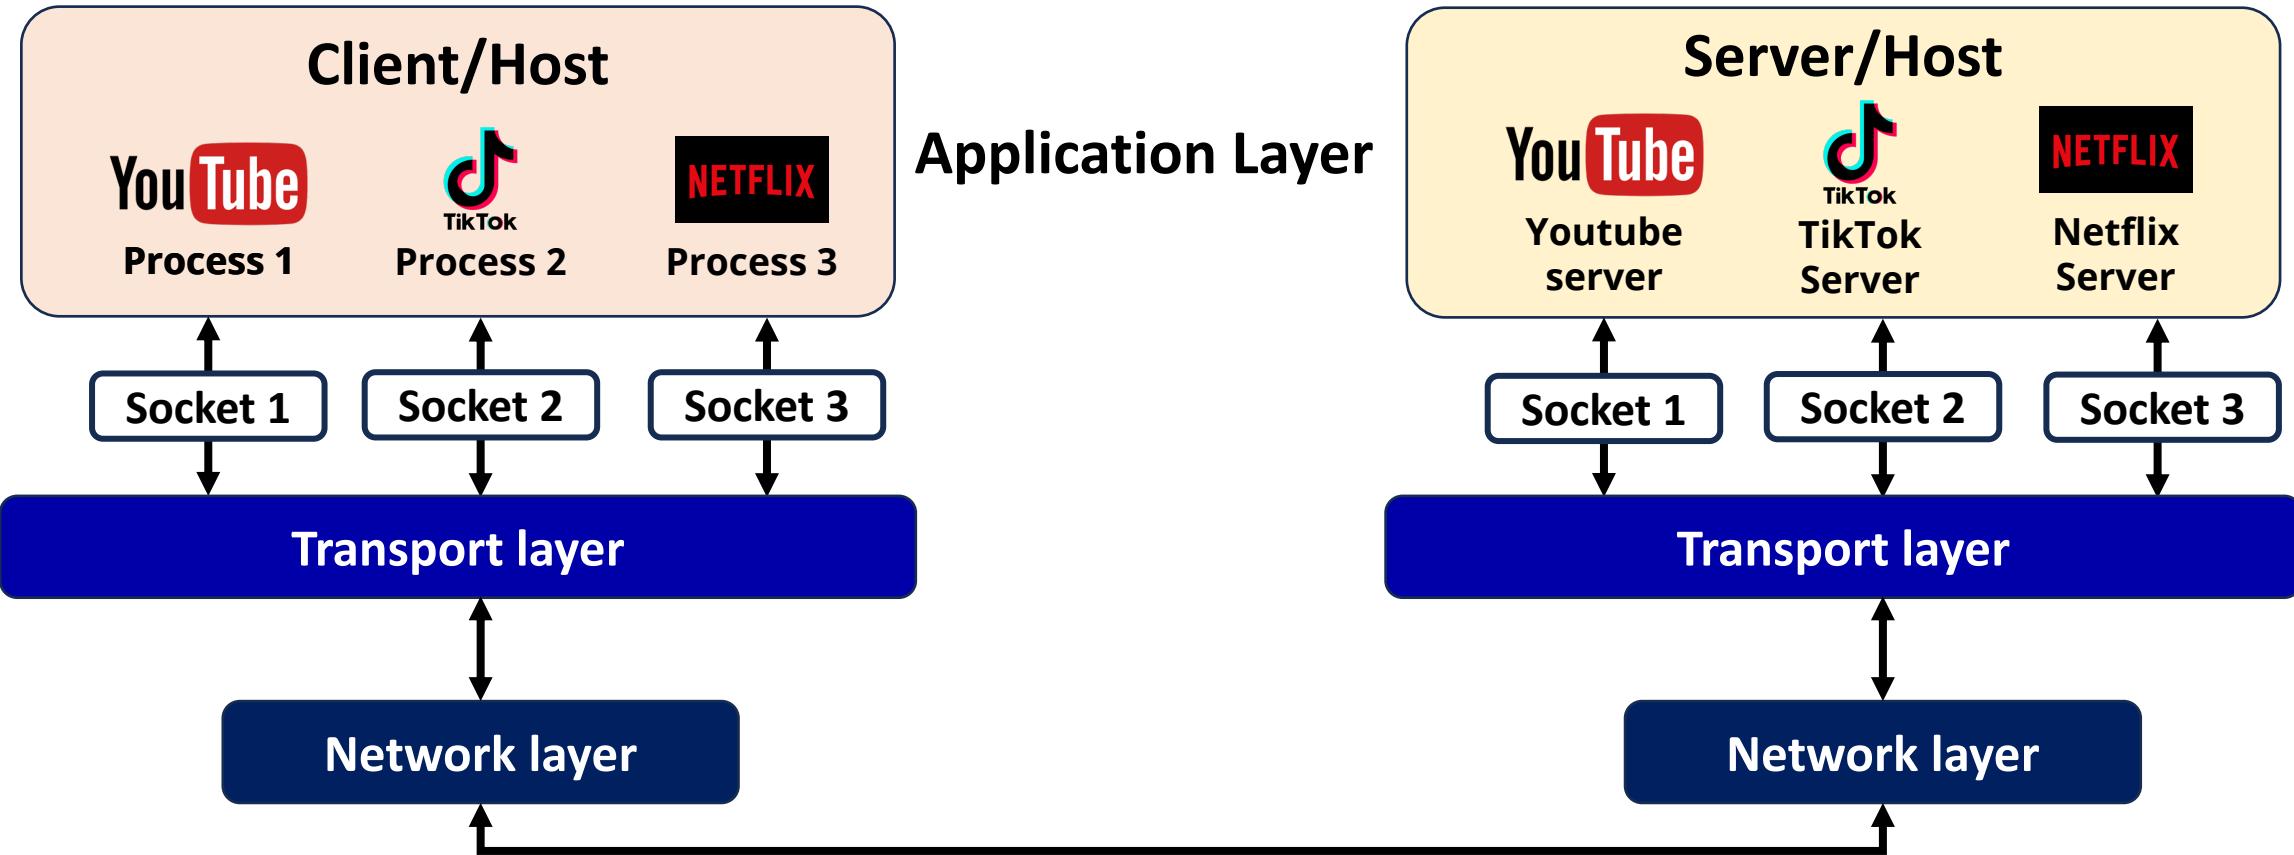

# Transport services and protocols

- provide *logical communication* between application processes running on different hosts
- transport protocols actions in end systems:
  - sender: breaks application messages into *segments*, passes to network layer
  - receiver: reassembles segments into messages, passes to application layer
- two transport protocols available to Internet applications
  - TCP, UDP

# Transport vs. network layer services and protocols

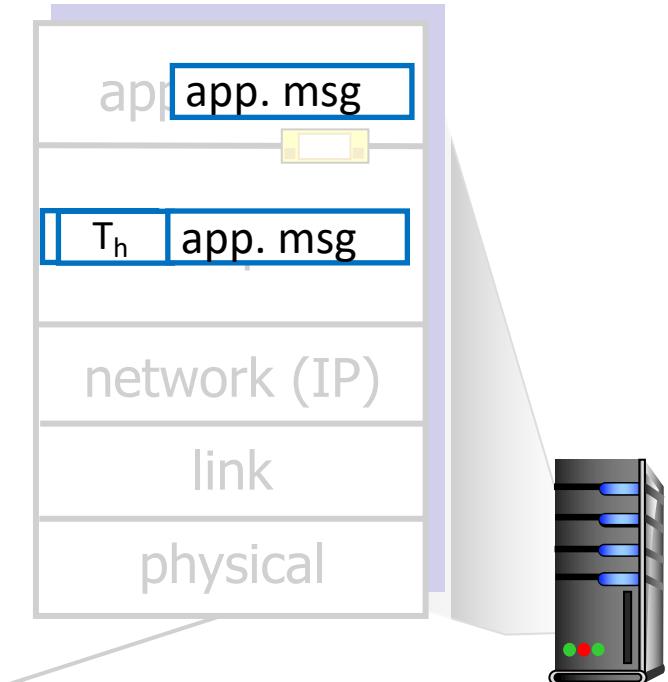

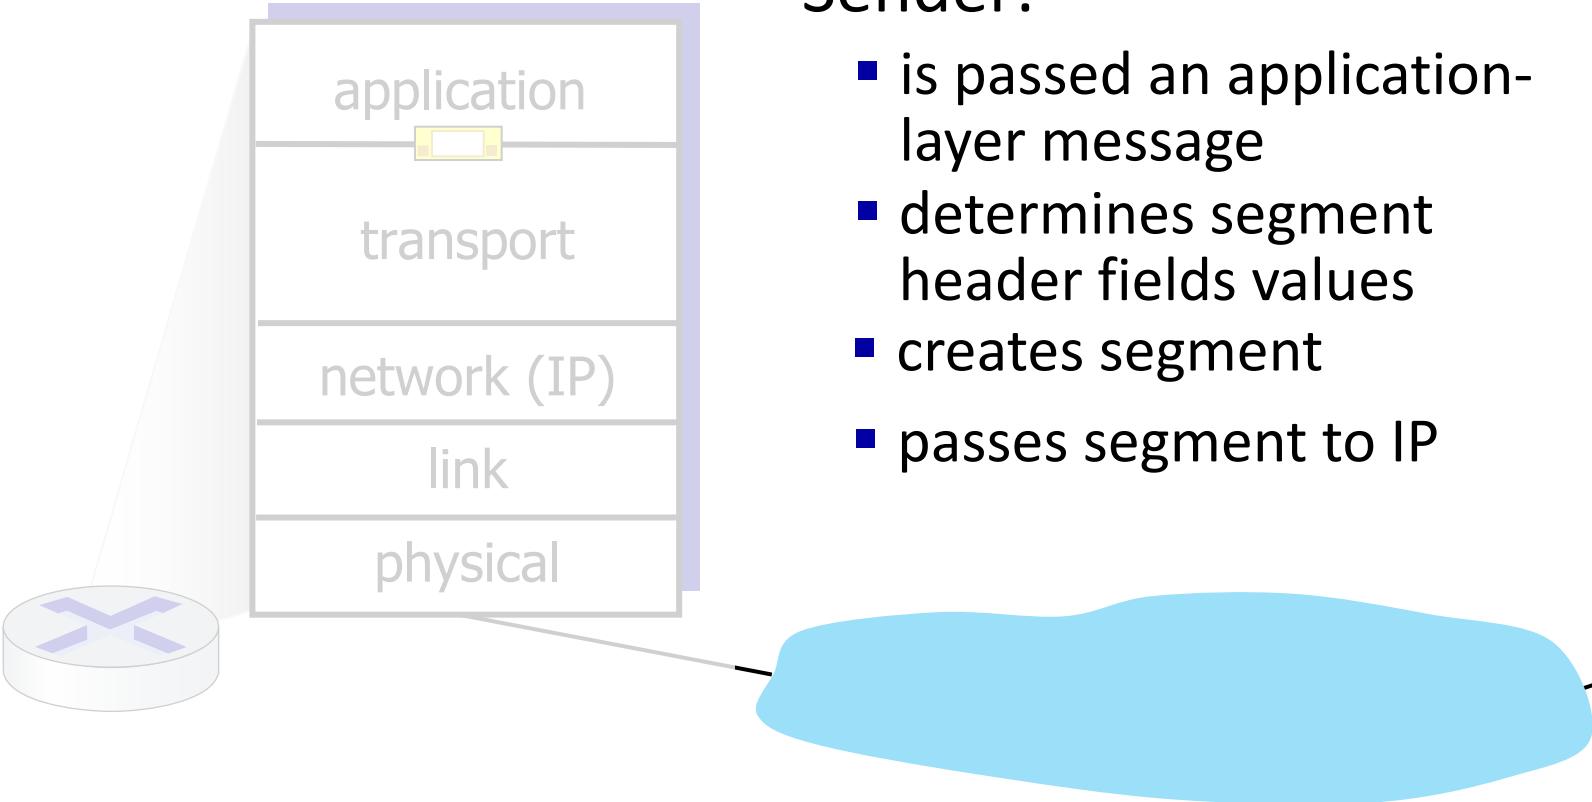

- **network layer:** communication between *hosts*

- **transport layer:** communication between *processes*
  - relies on, enhances, network layer services

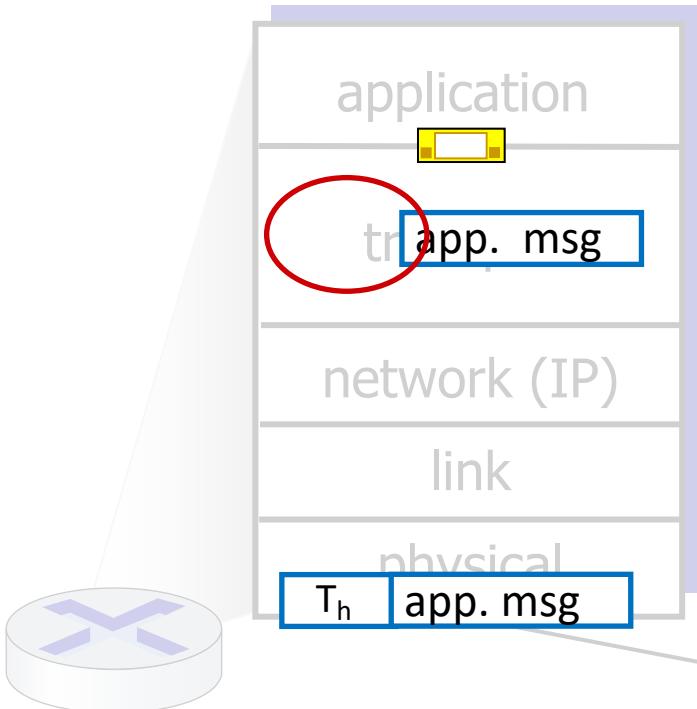

# Transport Layer Actions

Sender:

- is passed an application-layer message
- determines segment header fields values
- creates segment
- passes segment to IP

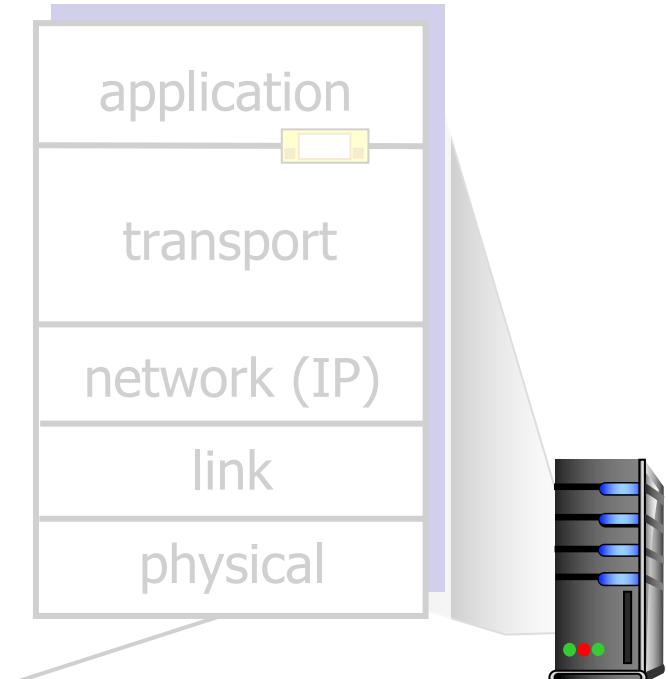

# Transport Layer Actions

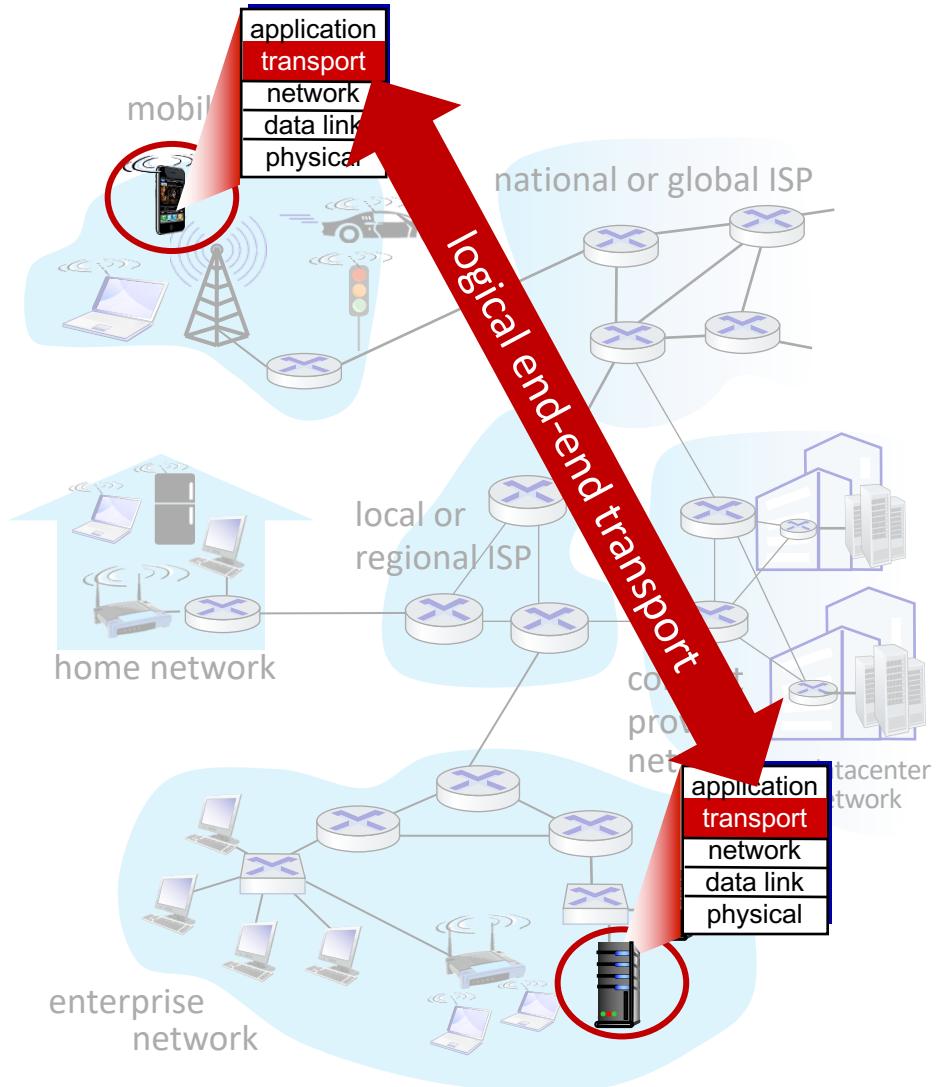

## Receiver:

- receives segment from IP
- checks header values
- extracts application-layer message
- **demultiplexes** message up to application via socket

# Two principal Internet transport protocols

- **TCP:** Transmission Control Protocol
  - reliable, in-order delivery
  - congestion control
  - flow control
  - connection setup
- **UDP:** User Datagram Protocol
  - unreliable, unordered delivery
  - no-frills extension of “best-effort” IP
- services *not* available:
  - delay guarantees
  - bandwidth guarantees

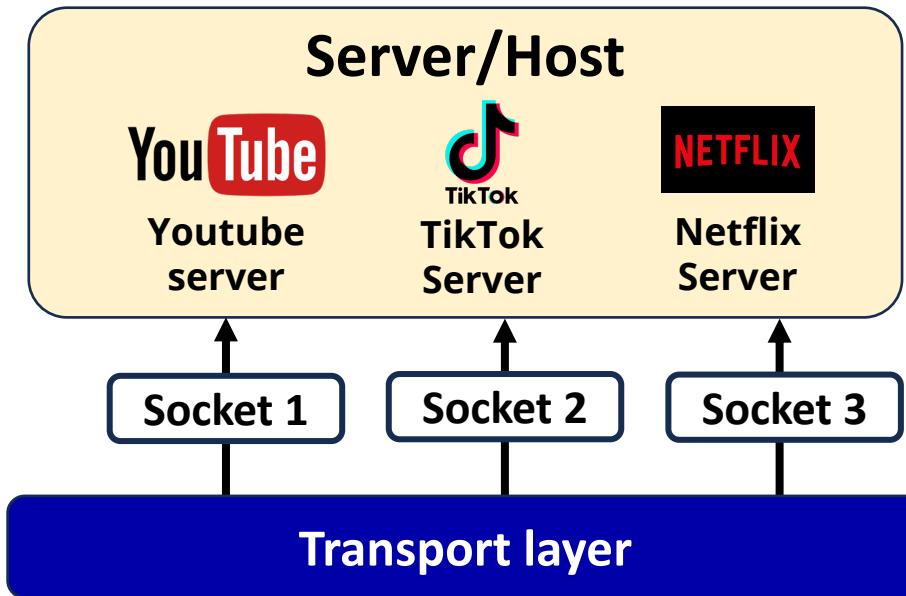

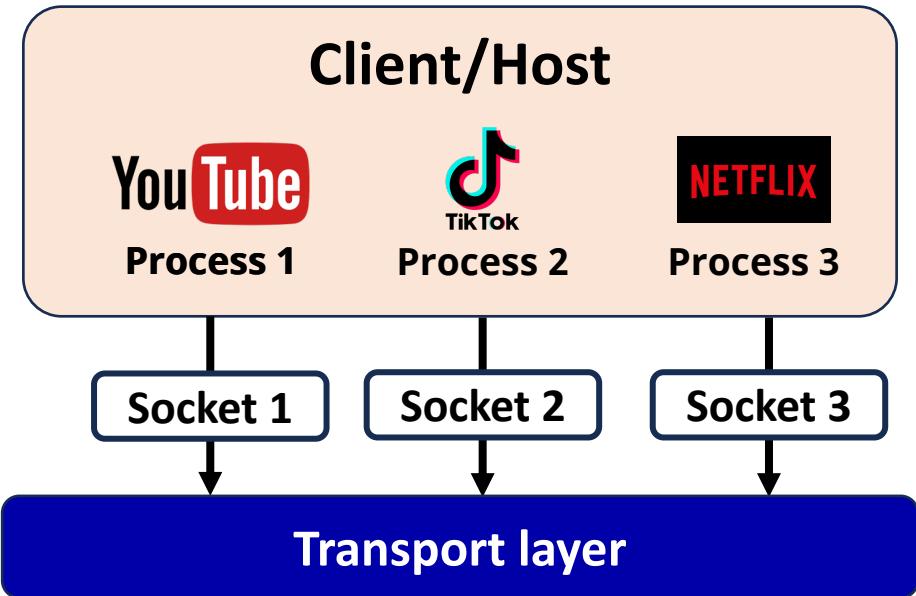

# Chapter 3: roadmap

- Transport-layer services
- **Multiplexing and demultiplexing**
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

# Multiplexing/demultiplexing

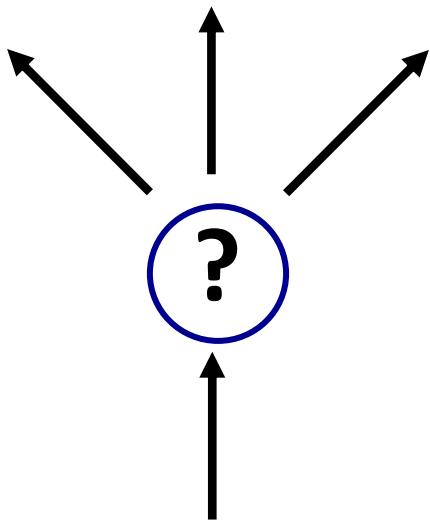

*multiplexing as sender:*

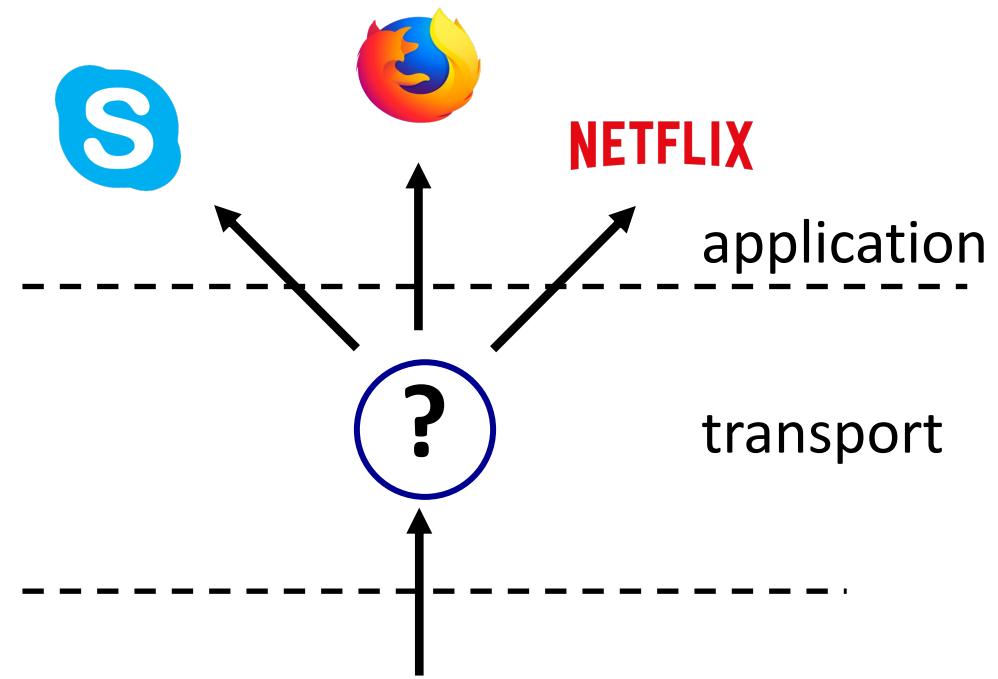

handle data from multiple  
sockets, add transport header  
(later used for demultiplexing)

*demultiplexing as receiver:*

use header info to deliver  
received segments to correct  
socket

de-multiplexing

de-multiplexing

# Demultiplexing

AIRFRANCE /

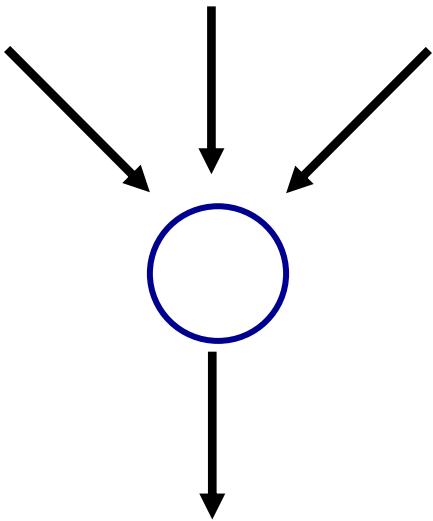

ECONOMY /

AIRFRANCE /

SKY  
PRIORITY™

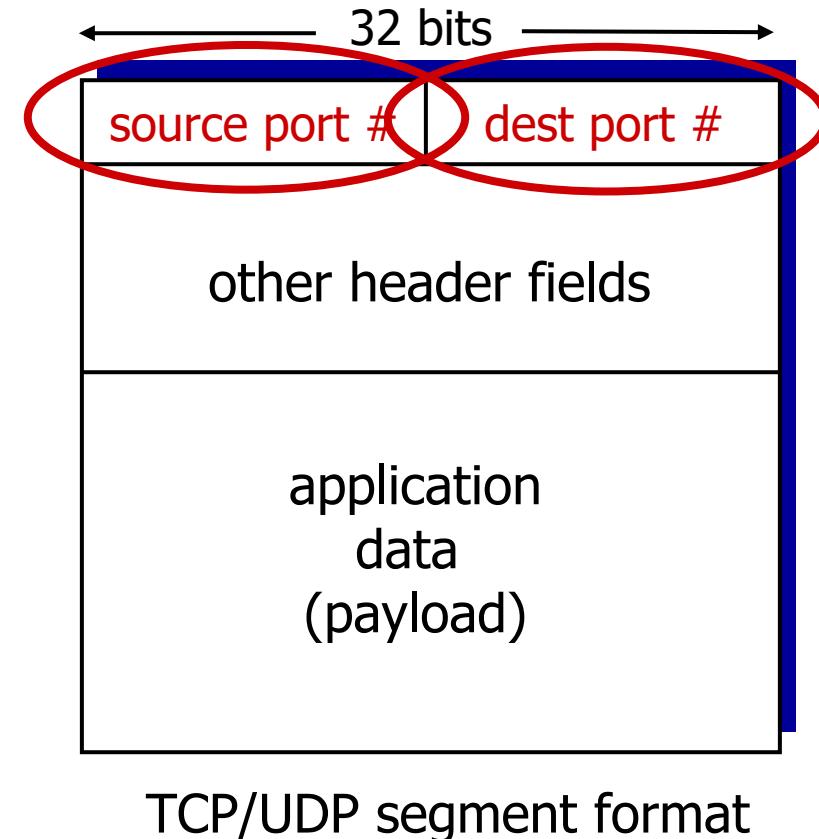

multiplexing

# How demultiplexing works

- host receives IP datagrams
  - each datagram has source IP address, destination IP address
  - each datagram carries one transport-layer segment
  - each segment has source, destination port number
- host uses *IP addresses & port numbers* to direct segment to appropriate socket

# Connectionless demultiplexing

Recall:

- when creating socket, must specify *host-local* port #:

```
DatagramSocket mySocket1  
= new DatagramSocket(12534);
```

- when creating datagram to send into UDP socket, must specify
  - destination IP address
  - destination port #

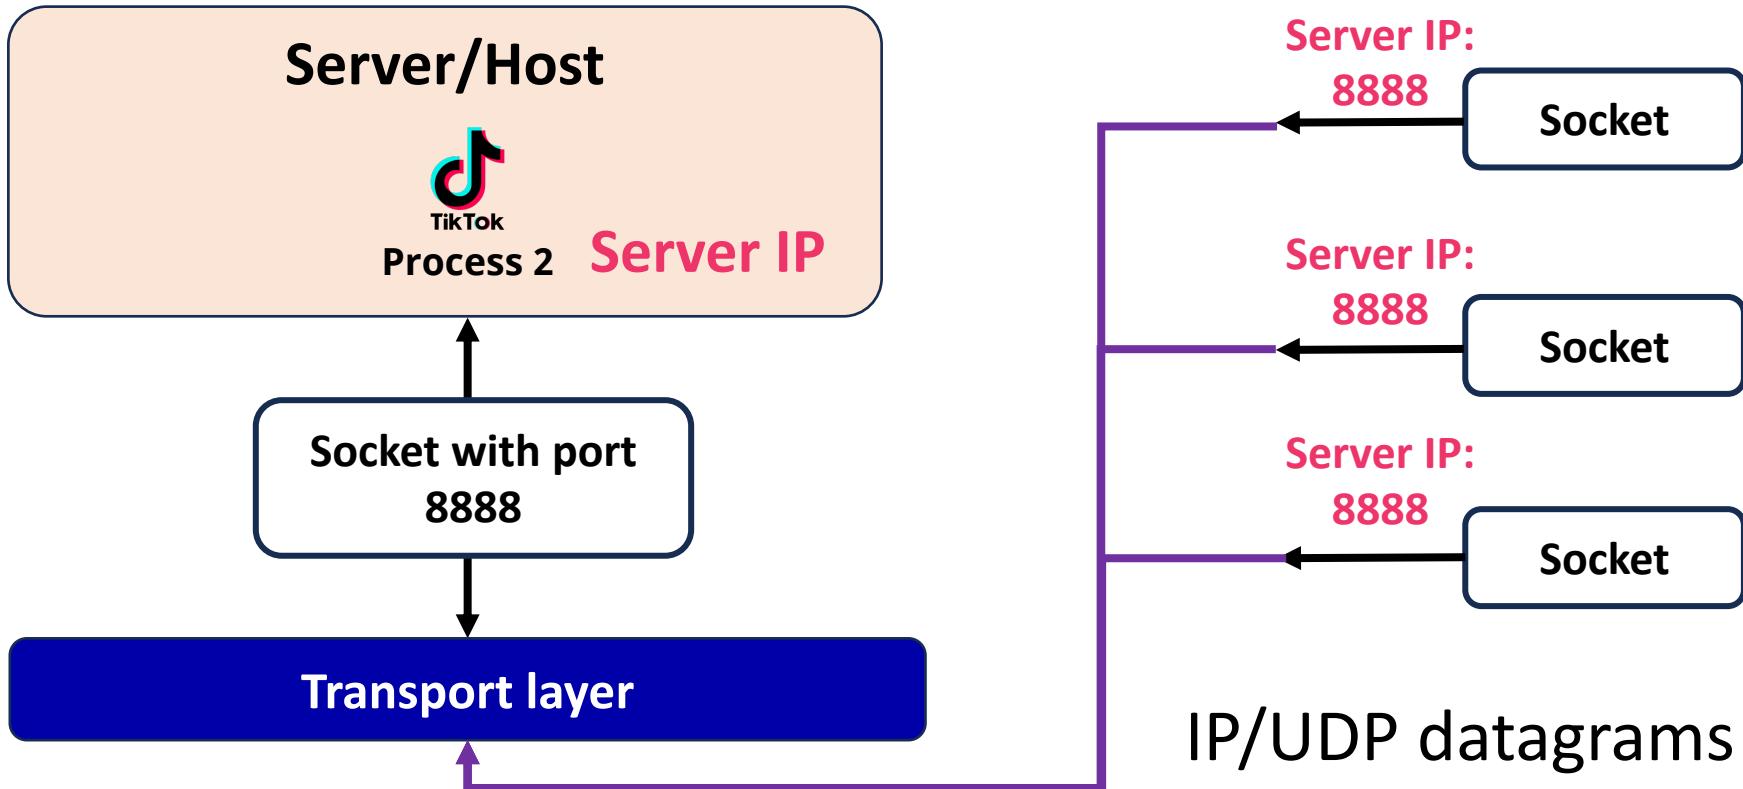

when receiving host receives UDP segment:

- checks destination port # in segment
- directs UDP segment to socket with that port #

IP/UDP datagrams with *same dest. port #*, but different source IP addresses and/or source port numbers will be directed to *same socket* at receiving host

# Connectionless demultiplexing

Process 2

Process 1

Process 3

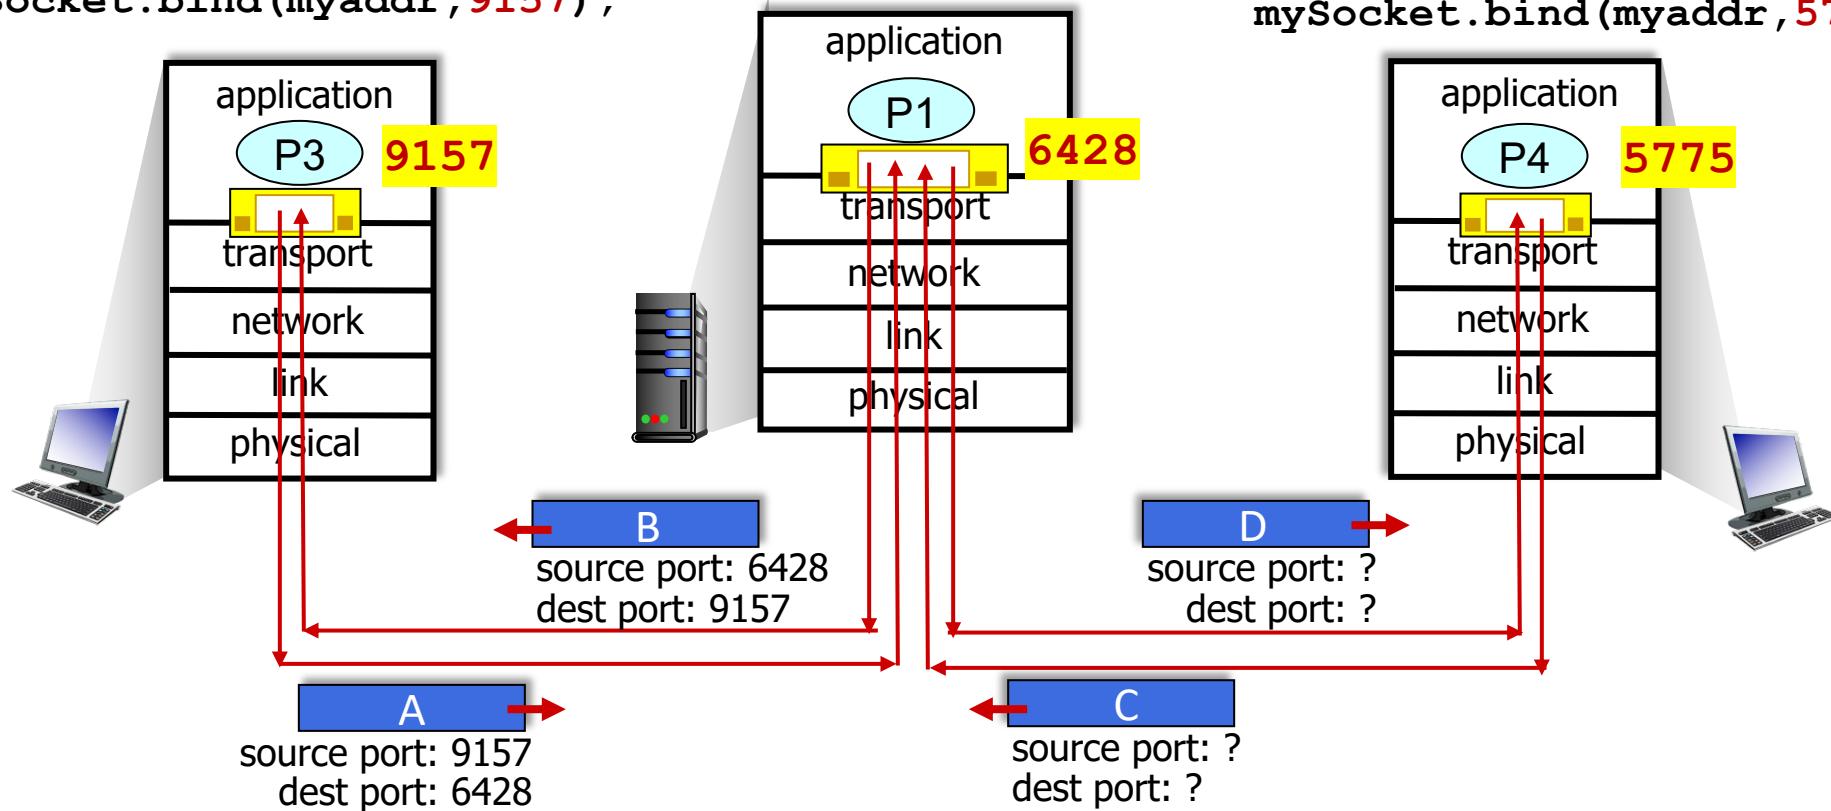

IP/UDP datagrams with *same dest. port #*, but different source IP addresses and/or source port numbers will be directed to *same socket* at receiving host

# Connectionless demultiplexing: an example

```
mySocket =  
    socket(AF_INET, SOCK_DGRAM)  
mySocket.bind(myaddr, 6428);
```

```
mySocket =  
    socket(AF_INET, SOCK_STREAM)  
mySocket.bind(myaddr, 9157);
```

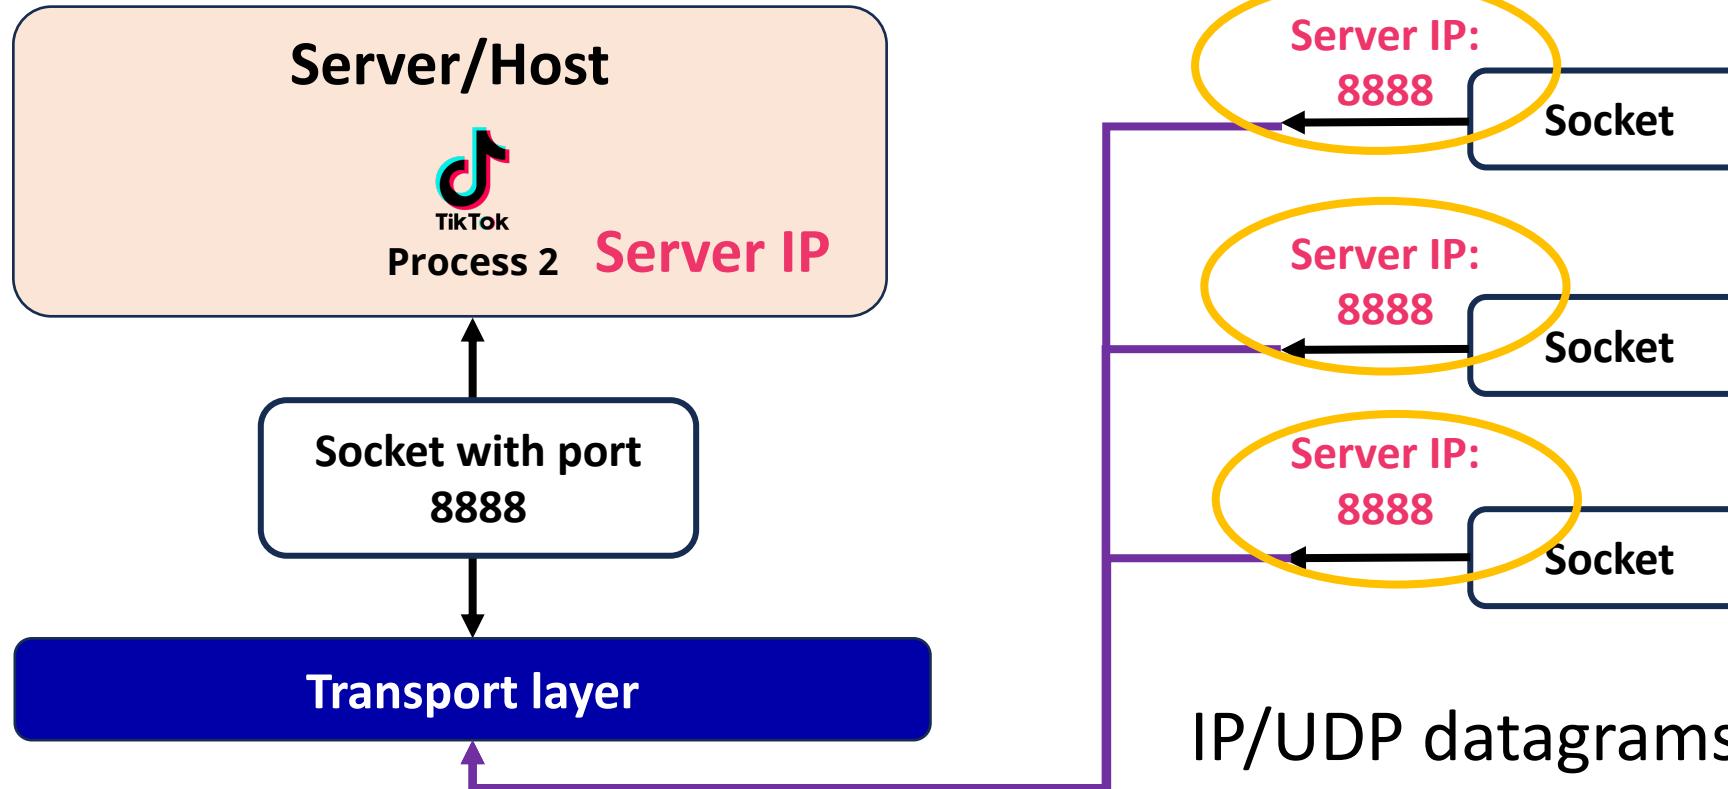

```
mySocket =  
    socket(AF_INET, SOCK_STREAM)  
mySocket.bind(myaddr, 5775);
```

# Connection-oriented demultiplexing

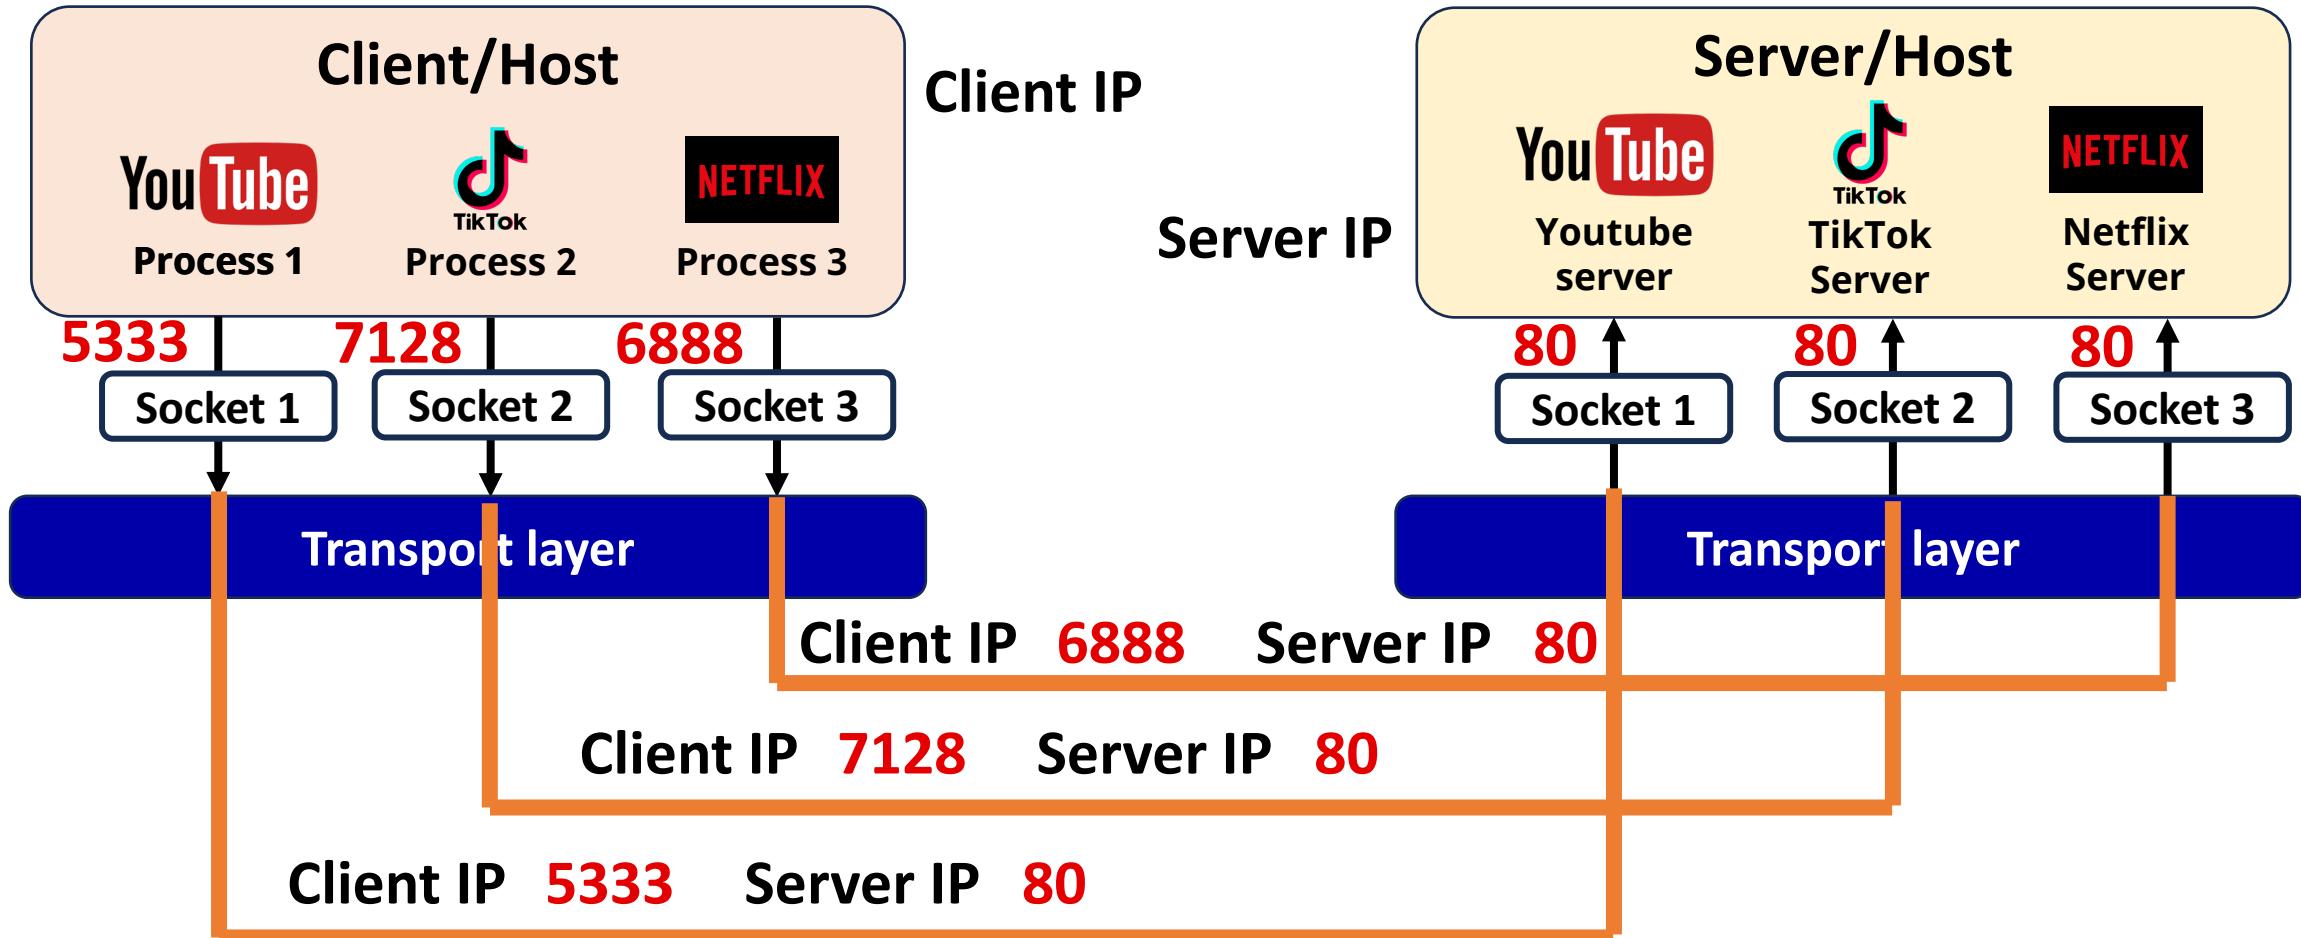

- TCP socket identified by **4-tuple**:
  - source IP address
  - source port number
  - dest IP address
  - dest port number
- demux: receiver uses *all four values (4-tuple)* to direct segment to appropriate socket
- server may support many simultaneous TCP sockets:
  - each socket identified by its own 4-tuple
  - each socket associated with a different connecting client

# Connectionless demultiplexing

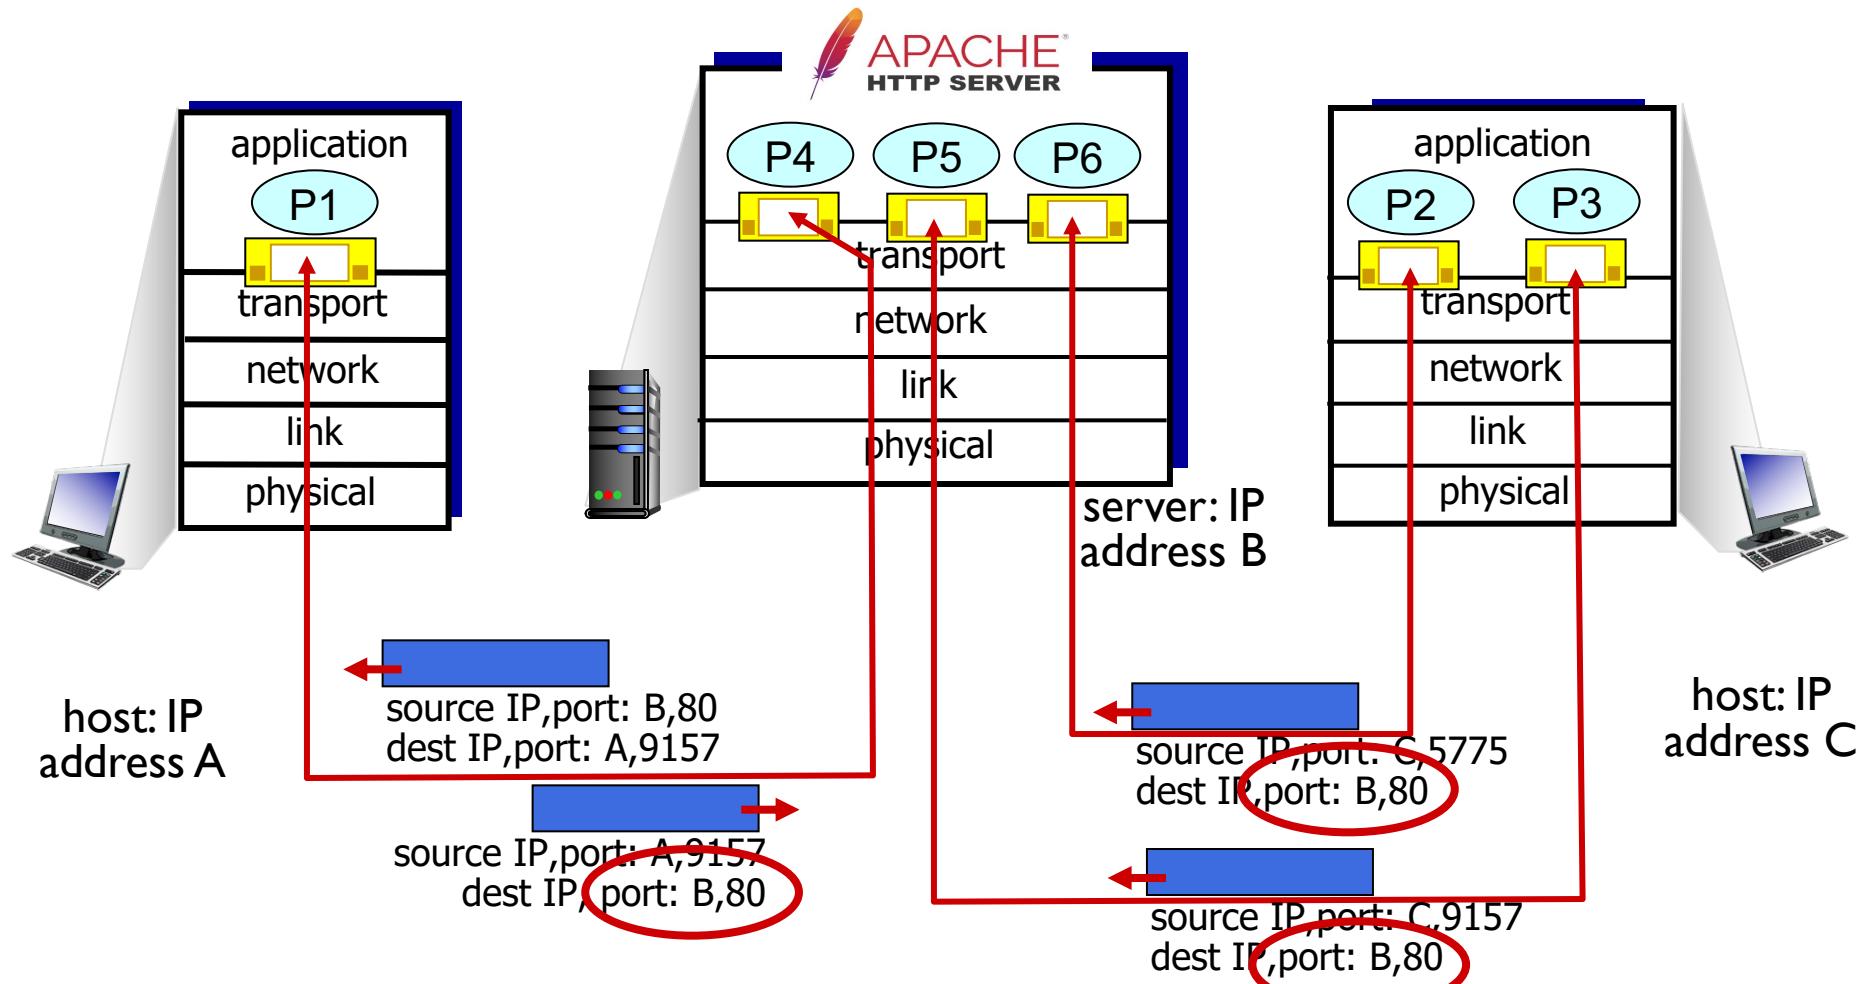

IP/UDP datagrams with *same dest. port #*, but different source IP addresses and/or source port numbers will be directed to *same socket* at receiving host

# Connection-oriented demultiplexing

*4-tuple matters here!*

# Connection-oriented demultiplexing: example

Three segments, all destined to IP address: B,  
dest port: 80 are demultiplexed to *different* sockets

# Summary

- Multiplexing, demultiplexing: based on segment, datagram header field values
- **UDP:** demultiplexing using destination port number (only)
- **TCP:** demultiplexing using 4-tuple: source and destination IP addresses, and port numbers
- Multiplexing/demultiplexing happen at *all* layers

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- **Connectionless transport: UDP**
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

# UDP: User Datagram Protocol

- “no frills,” “bare bones” Internet transport protocol
- “best effort” service, UDP segments may be:
  - lost
  - delivered out-of-order to app
- *connectionless*:
  - no handshaking between UDP sender, receiver
  - each UDP segment handled independently of others

## Why is there a UDP?

- no connection establishment (which can add RTT delay)
- simple: no connection state at sender, receiver
- small header size
- no congestion control
  - UDP can blast away as fast as desired!
  - can function in the face of congestion

# UDP: User Datagram Protocol

- UDP use:
  - streaming multimedia apps (loss tolerant, rate sensitive)
  - DNS
  - SNMP
  - HTTP/3
- if reliable transfer needed over UDP (e.g., HTTP/3):
  - add needed reliability at application layer
  - add congestion control at application layer

# UDP: User Datagram Protocol [RFC 768]

INTERNET STANDARD  
RFC 768 J. Postel

28 August 1980

## User Datagram Protocol

---

### Introduction

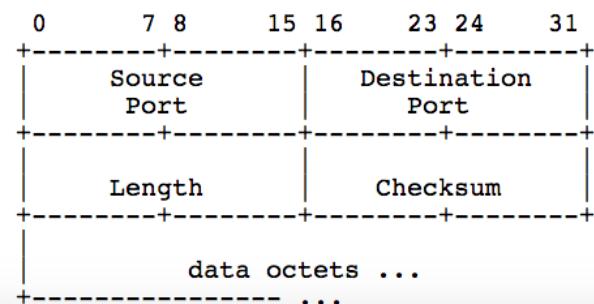

---

This User Datagram Protocol (UDP) is defined to make available a datagram mode of packet-switched computer communication in the environment of an interconnected set of computer networks. This protocol assumes that the Internet Protocol (IP) [1] is used as the underlying protocol.

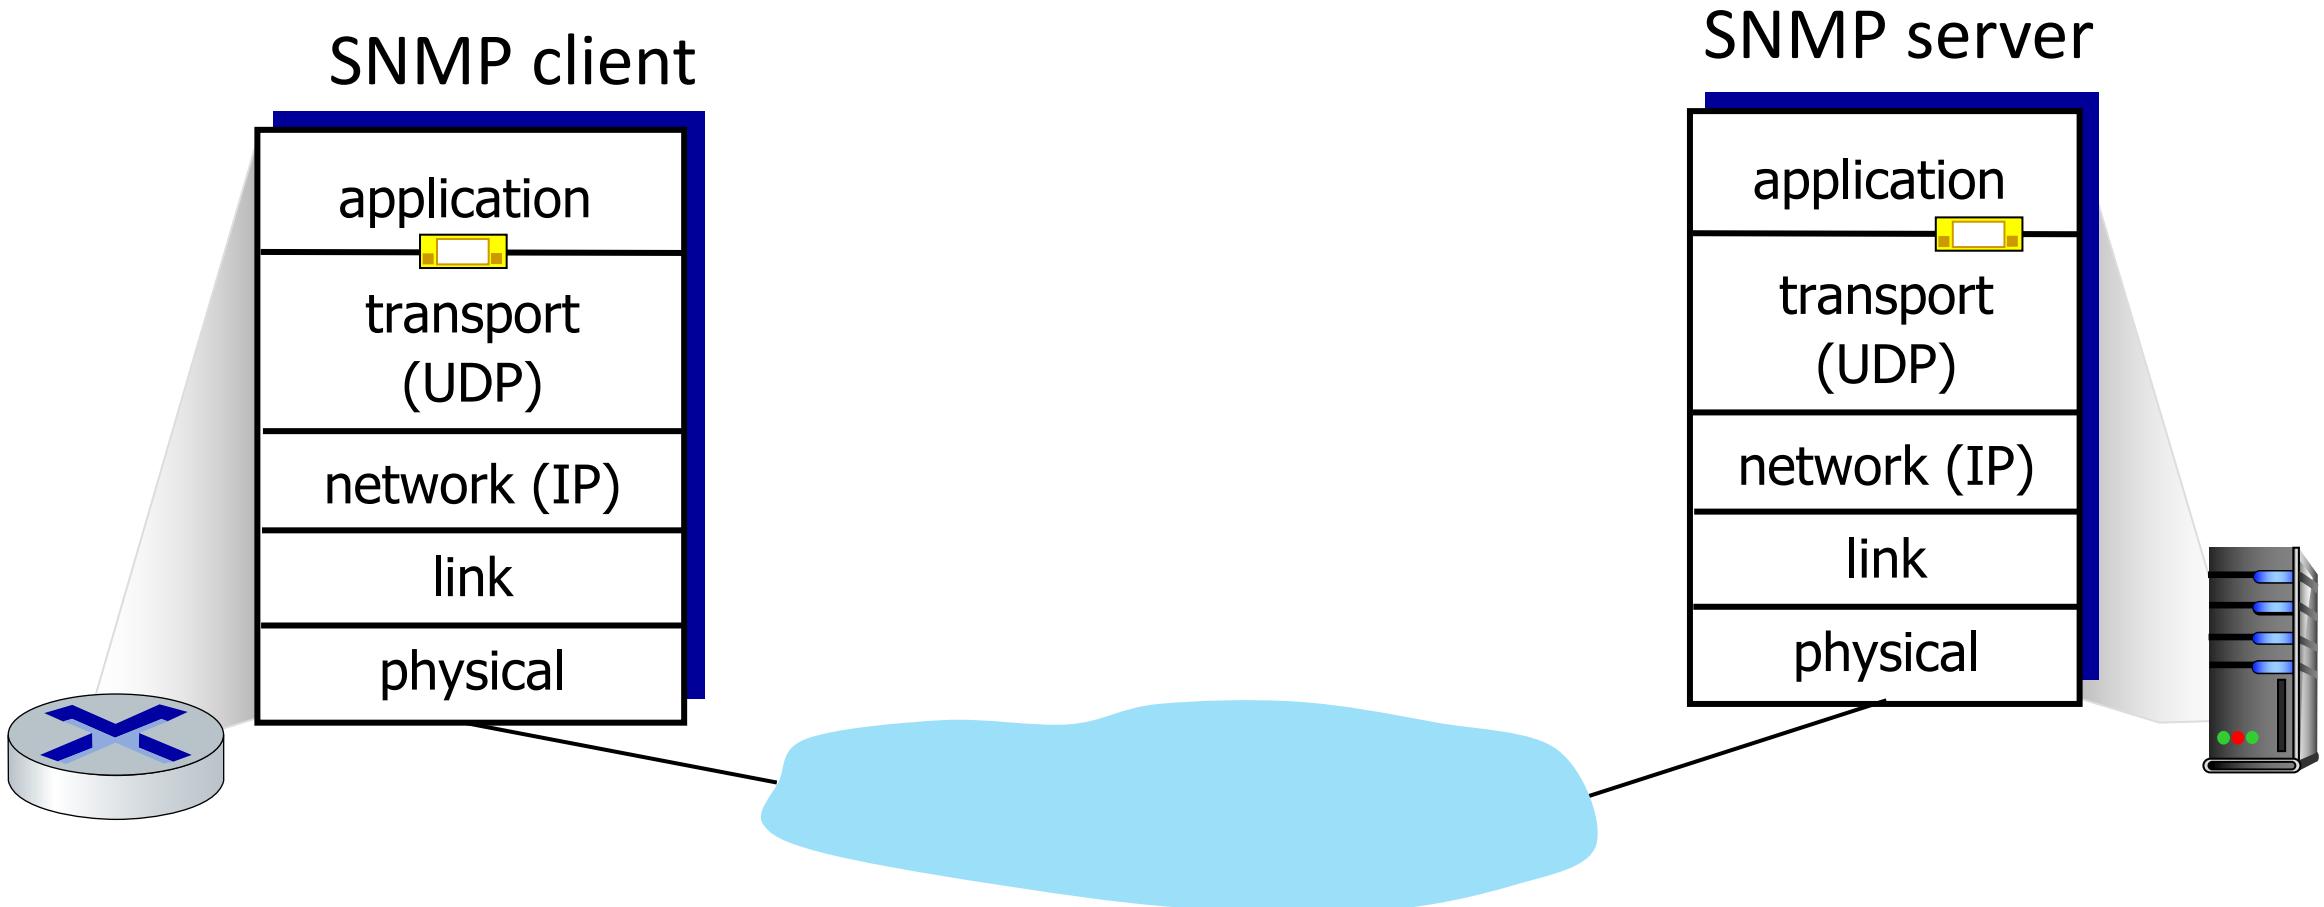

This protocol provides a procedure for application programs to send messages to other programs with a minimum of protocol mechanism. The protocol is transaction oriented, and delivery and duplicate protection are not guaranteed. Applications requiring ordered reliable delivery of streams of data should use the Transmission Control Protocol (TCP) [2].

### Format

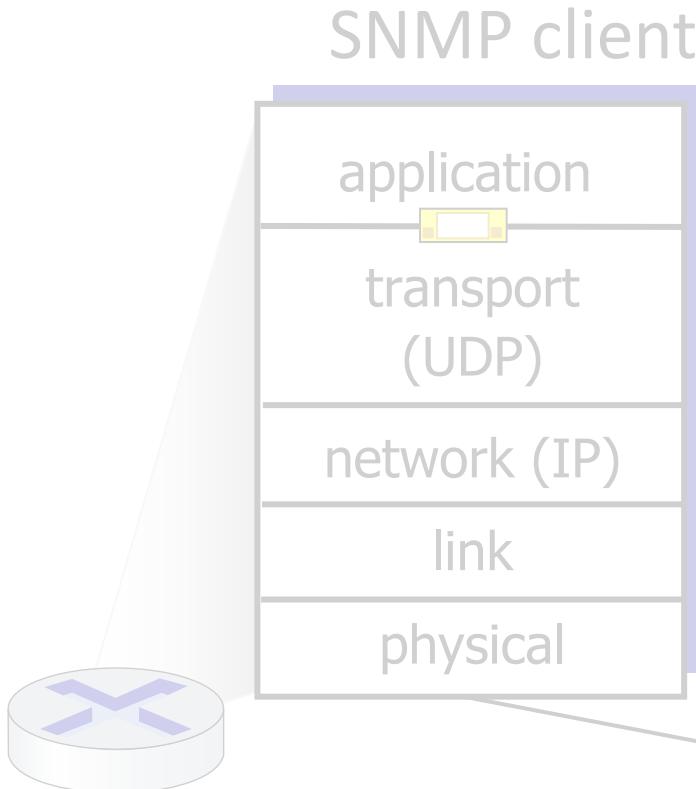

---

# UDP: Transport Layer Actions

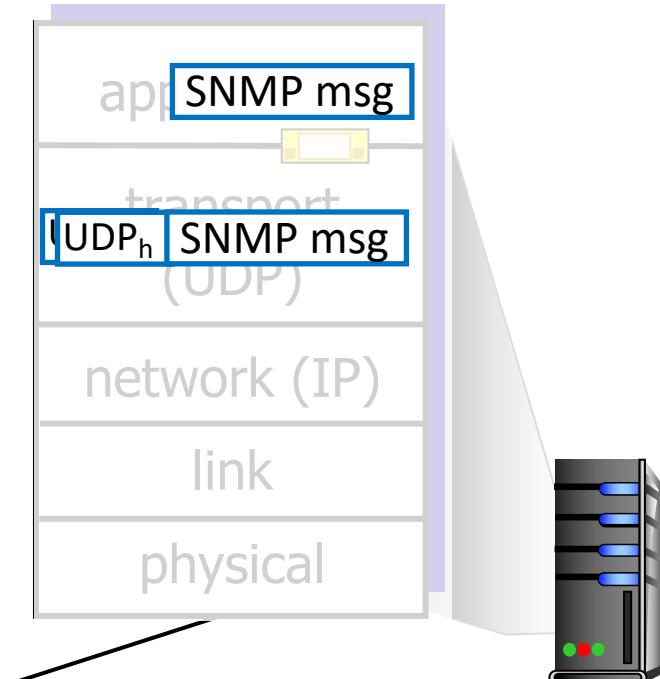

# UDP: Transport Layer Actions

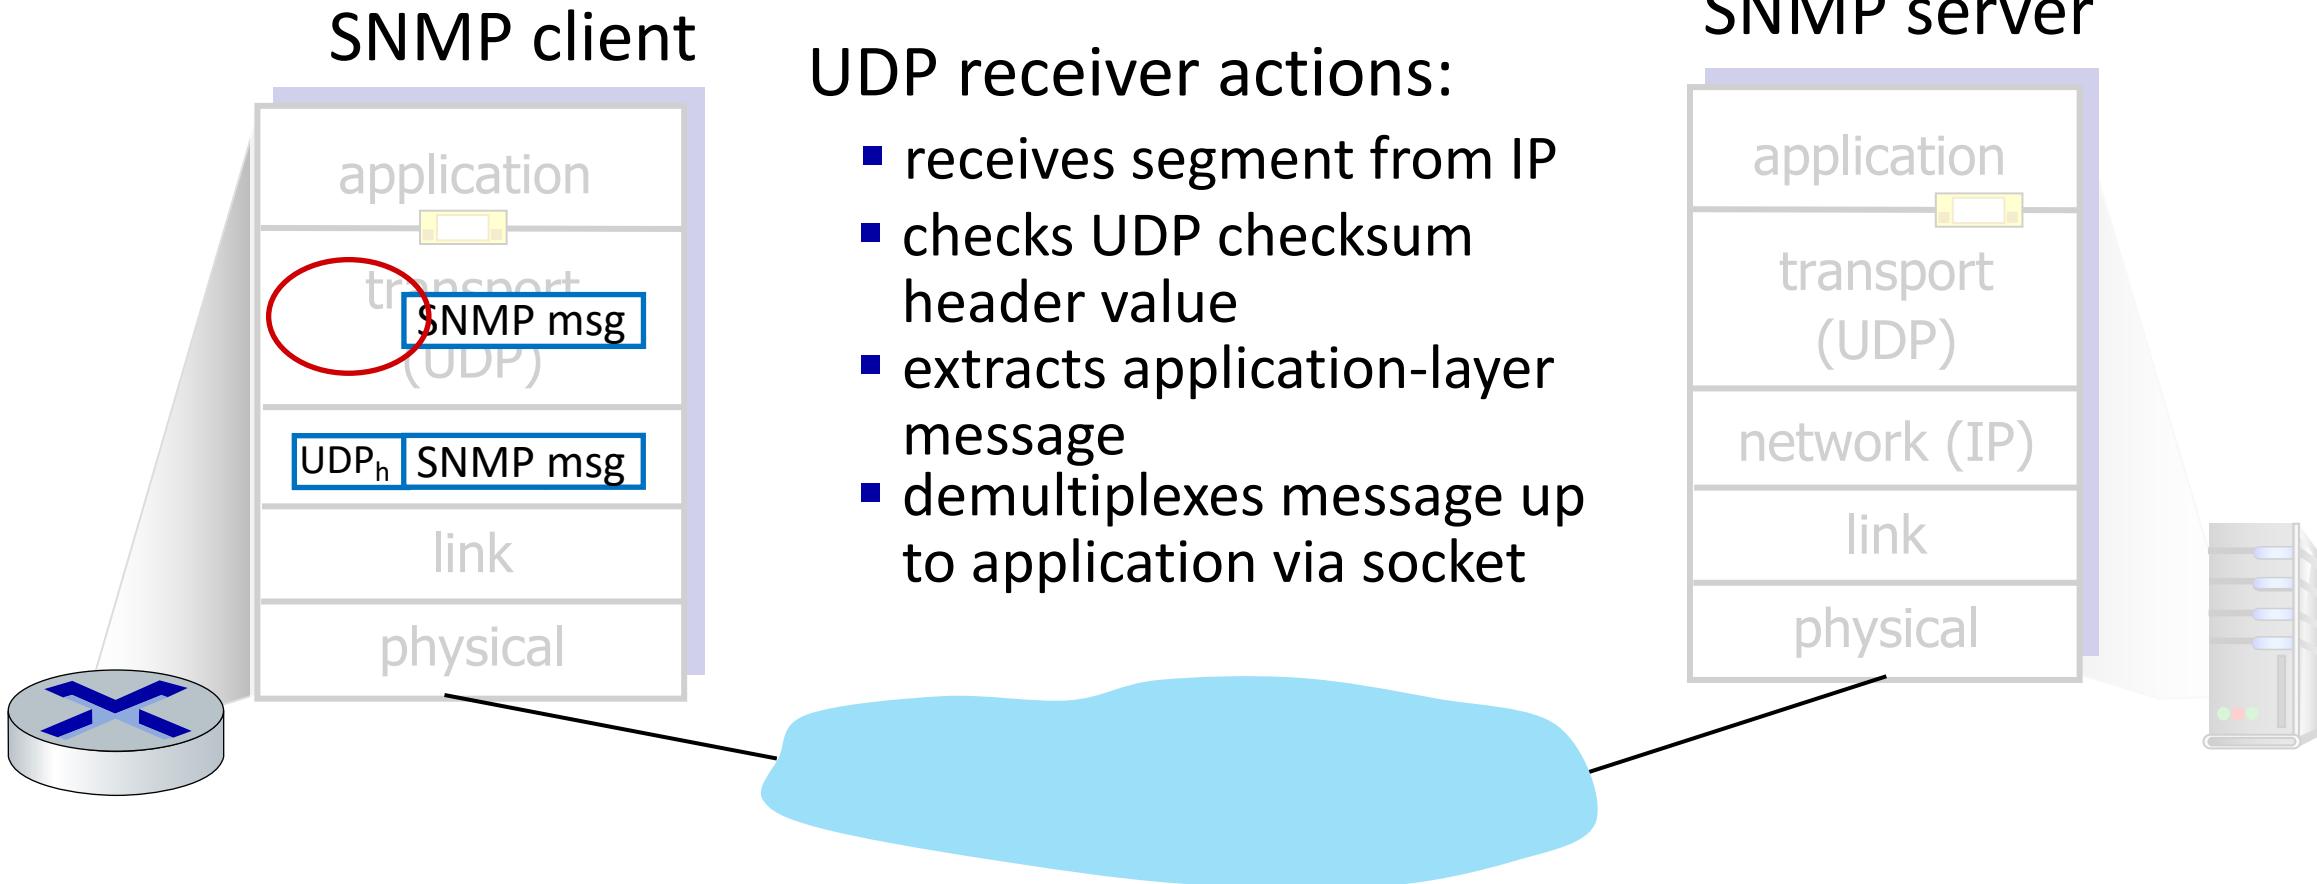

## UDP sender actions:

- is passed an application-layer message
- determines UDP segment header fields values
- creates UDP segment
- passes segment to IP

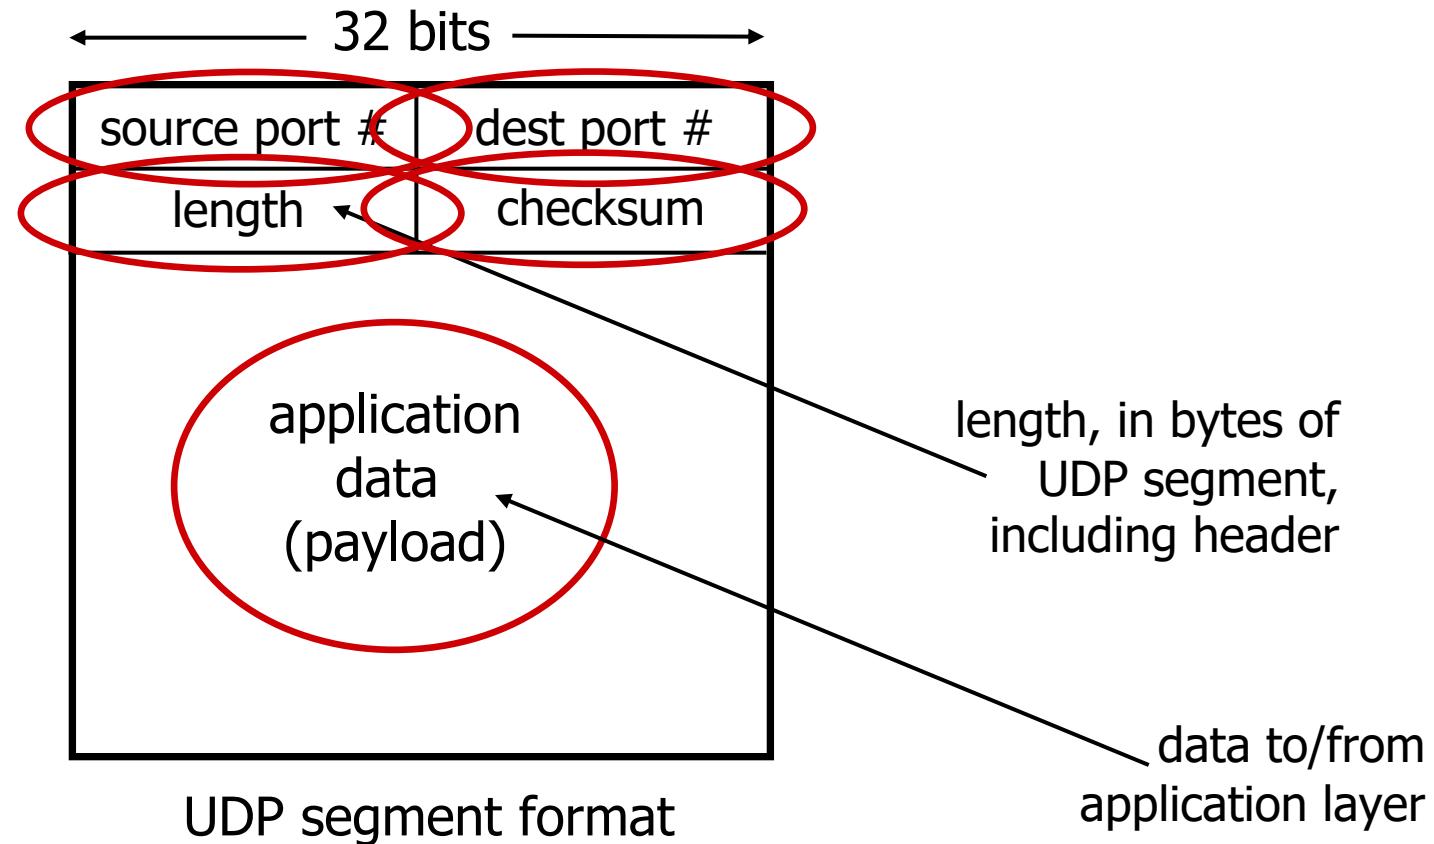

## SNMP server

# UDP: Transport Layer Actions

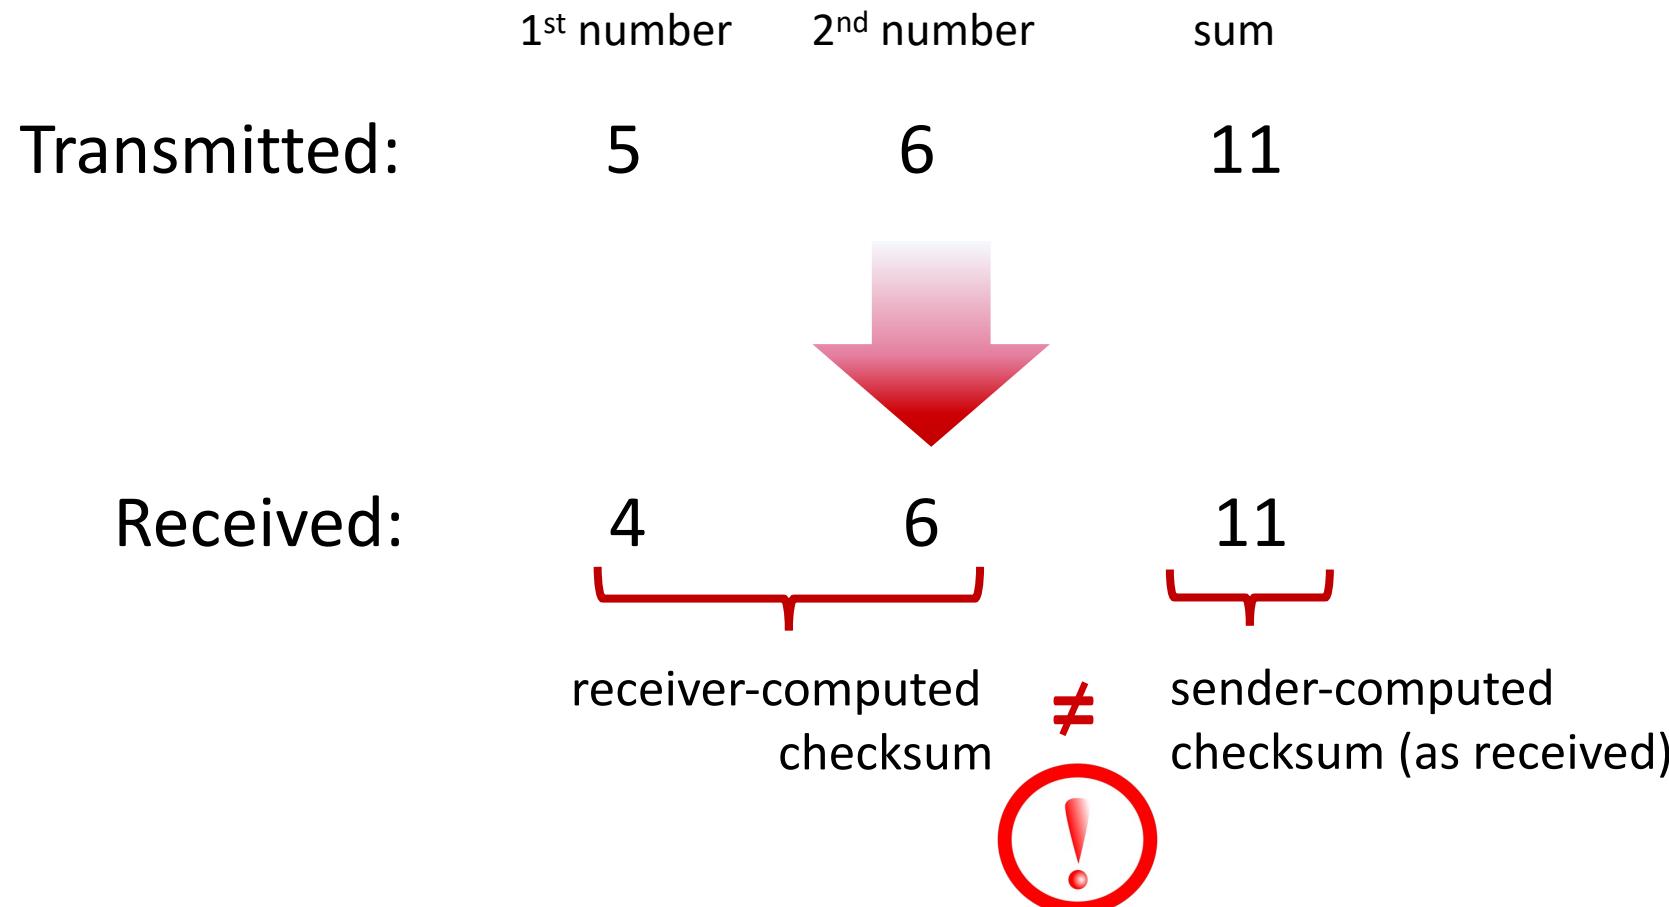

# UDP segment header

# UDP checksum

**Goal:** detect errors (*i.e.*, flipped bits) in transmitted segment

# Internet checksum

**Goal:** detect errors (*i.e.*, flipped bits) in transmitted segment

## sender:

- treat contents of UDP segment (including UDP header fields and IP addresses) as sequence of 16-bit integers
- **checksum:** addition (one's complement sum) of segment content
- checksum value put into UDP checksum field

## receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
  - not equal - error detected
  - equal - no error detected. *But maybe errors nonetheless? More later ...*

# Internet checksum: an example

example: add two 16-bit integers

	1	1	1	0	0	1	1	0	0	1	1	0	0	1	1	0
	1	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1
<hr/>																
wraparound	1	1	0	1	1	1	0	1	1	1	0	1	1	1	0	1
<hr/>																
sum	1	0	1	1	1	0	1	1	1	0	1	1	1	1	0	0
checksum	0	1	0	0	0	1	0	0	0	1	0	0	0	0	1	1

Note: when adding numbers, a carryout from the most significant bit needs to be added to the result

\* Check out the online interactive exercises for more examples: [http://gaia.cs.umass.edu/kurose\\_ross/interactive/](http://gaia.cs.umass.edu/kurose_ross/interactive/)

# Internet checksum: weak protection!

example: add two 16-bit integers

	1	1	1	0	0	1	1	0	0	1	1	0	0	1	1	0	1	0	1
	1	1	0	1	0	1	0	1	0	1	0	1	0	1	1	0	1	0	1
<hr/>																			
wraparound	1	1	0	1	1	1	0	1	1	1	0	1	1	1	0	1	1	0	1
sum	1	0	1	1	1	0	1	1	1	0	1	1	1	1	1	0	0	0	0
checksum	0	1	0	0	0	1	0	0	0	1	0	0	0	0	0	1	1	0	0

Even though numbers have changed (bit flips), *no* change in checksum!

# Summary: UDP

- “no frills” protocol:
  - segments may be lost, delivered out of order
  - best effort service: “send and hope for the best”
- UDP has its plusses:
  - no setup/handshaking needed (no RTT incurred)
  - can function when network service is compromised
  - helps with reliability (checksum)
- build additional functionality on top of UDP in application layer (e.g., HTTP/3)

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- **Principles of reliable data transfer**
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

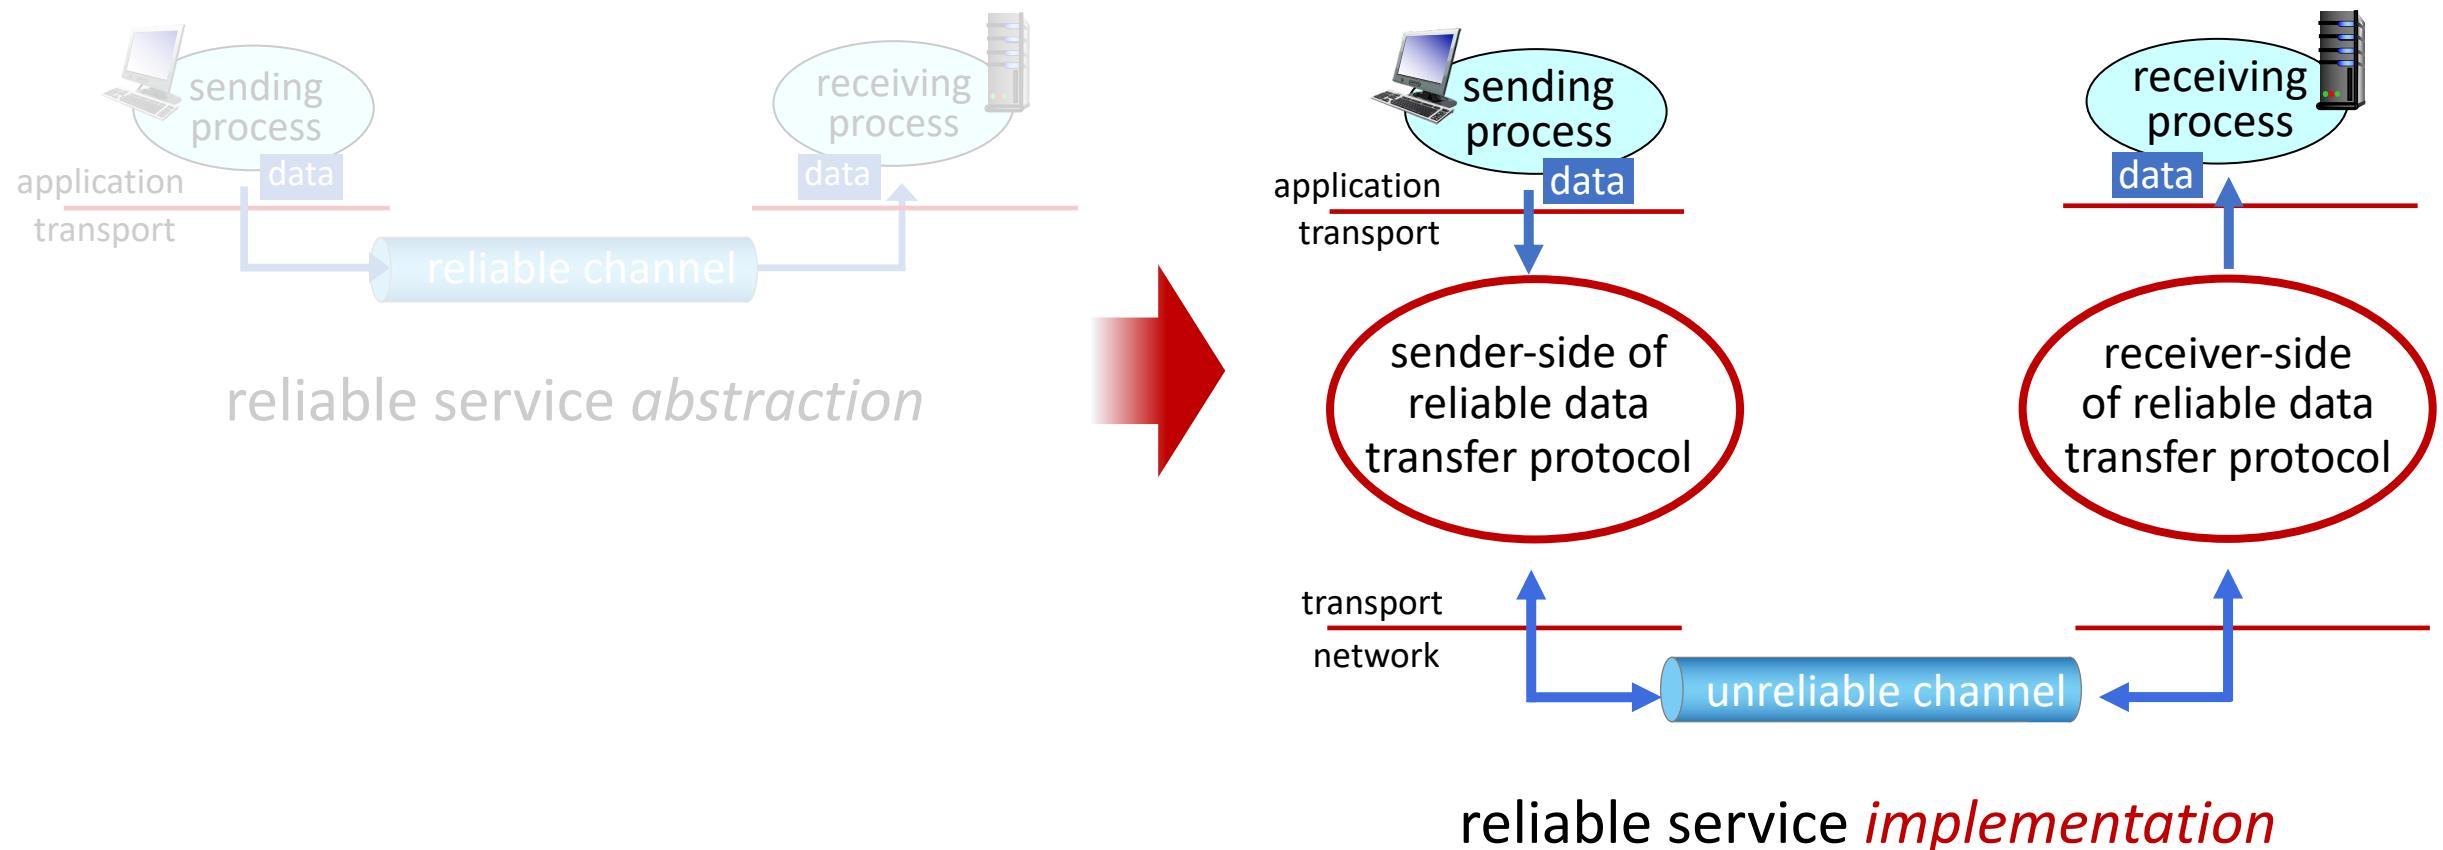

# Principles of reliable data transfer

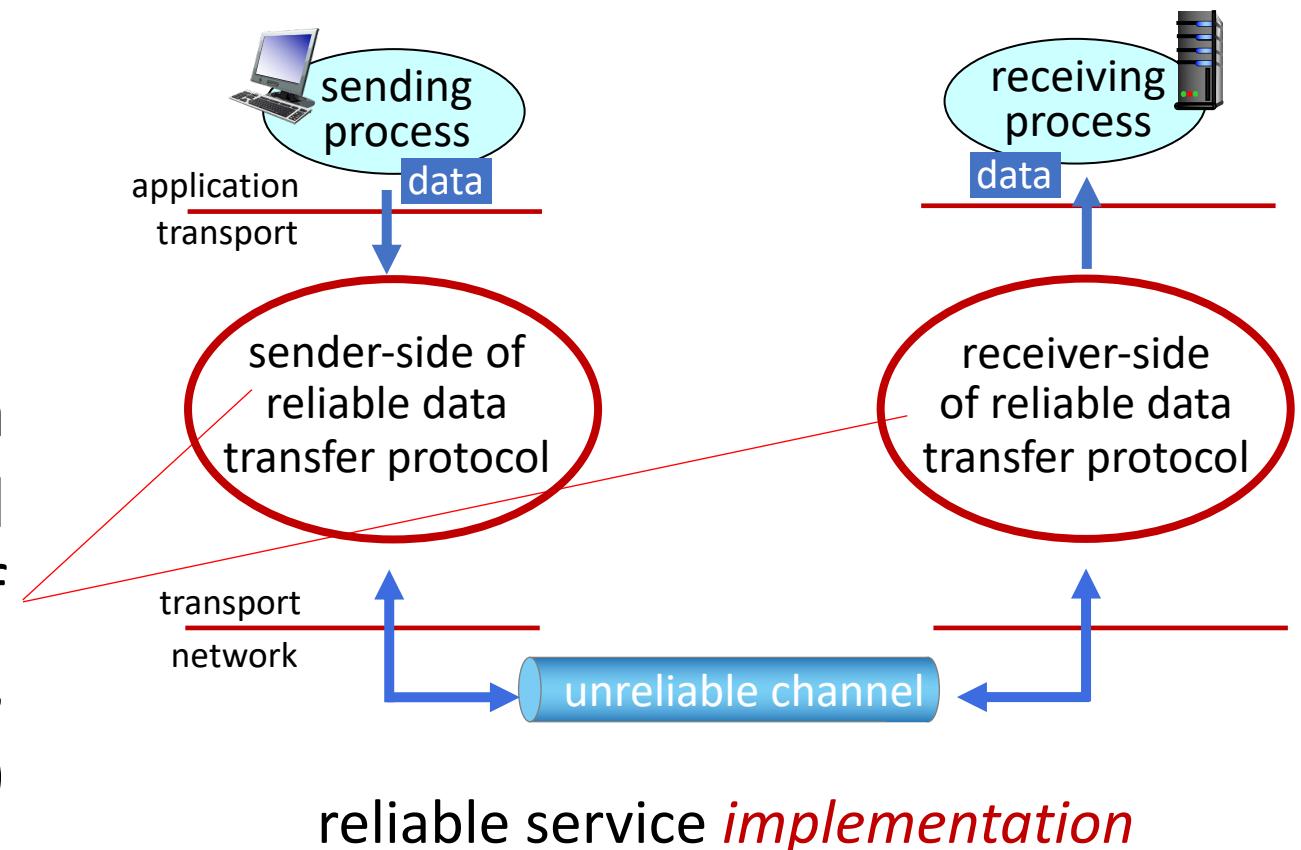

reliable service *abstraction*

# Principles of reliable data transfer

# Principles of reliable data transfer

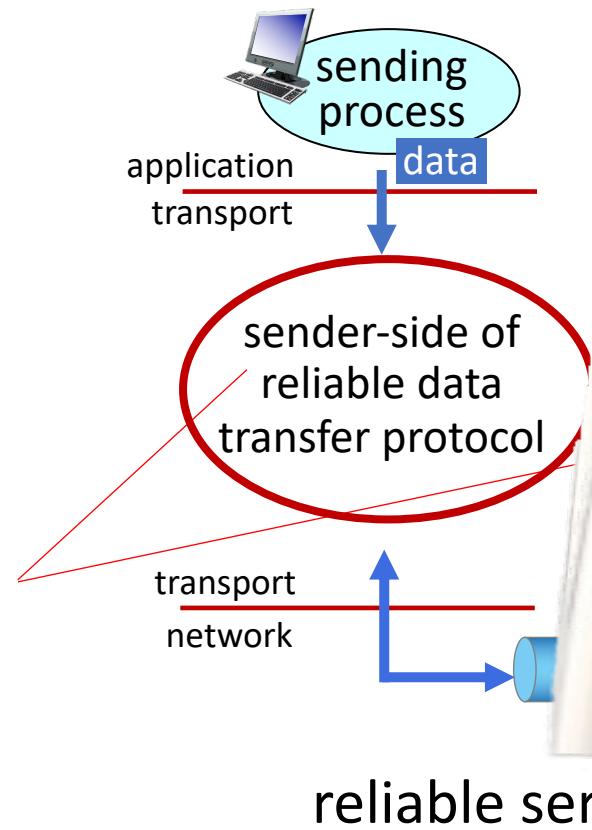

Complexity of reliable data transfer protocol will depend (strongly) on characteristics of unreliable channel (lose, corrupt, reorder data?)

# Principles of reliable data transfer

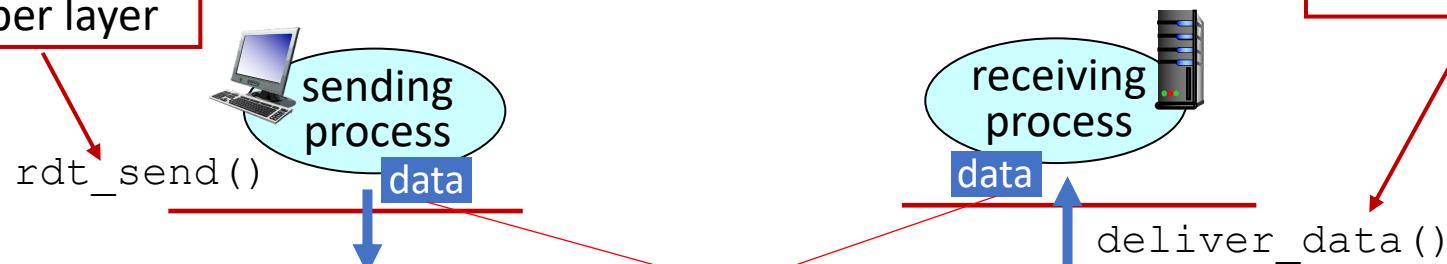

Sender, receiver do *not* know the “state” of each other, e.g., was a message received?

- unless communicated via a message

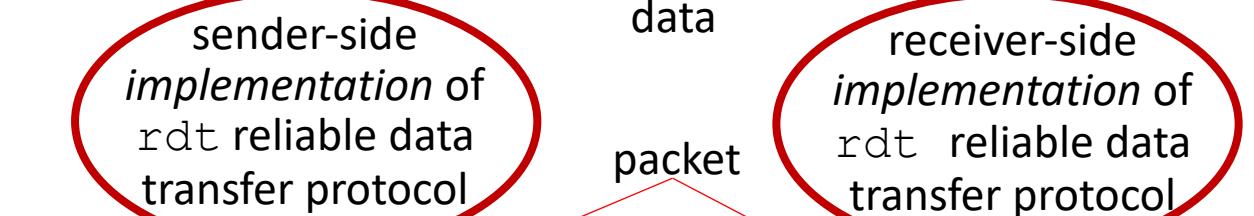

# Reliable data transfer protocol (rdt): interfaces

**rdt\_send():** called from above, (e.g., by app.). Passed data to deliver to receiver upper layer

**deliver\_data():** called by rdt to deliver data to upper layer

**udt\_send():** called by rdt to transfer packet over unreliable channel to receiver

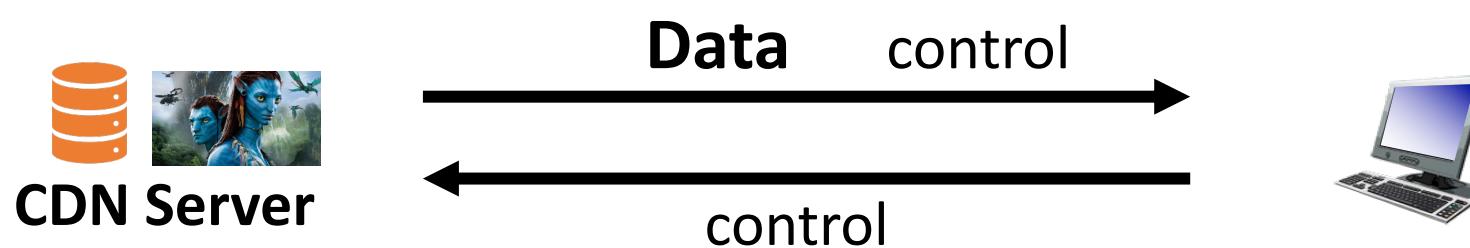

Bi-directional communication over unreliable channel

**rdt\_rcv():** called when packet arrives on receiver side of channel

# Reliable data transfer: getting started

We will:

- incrementally develop sender, receiver sides of reliable data transfer protocol (rdt)
- consider only unidirectional data transfer
  - but control info will flow in both directions!

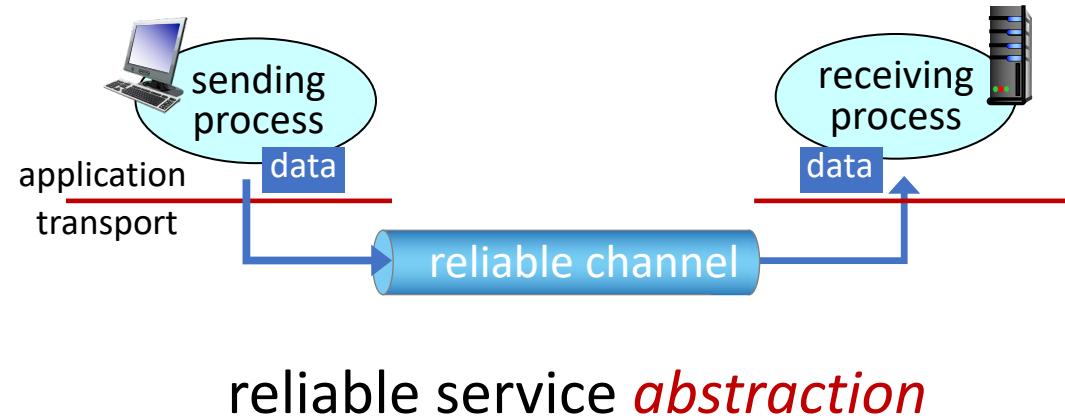

# Reliable data transfer: Protocol States

- use finite state machines (FSM) to specify sender, receiver

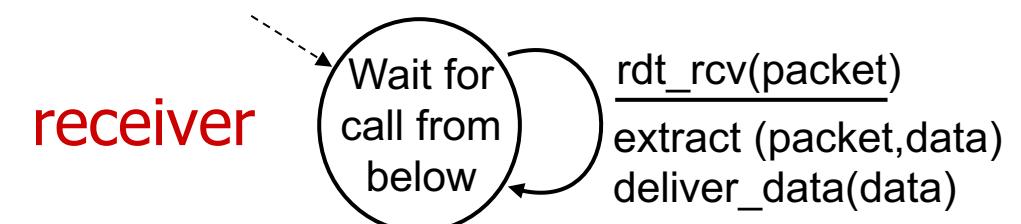

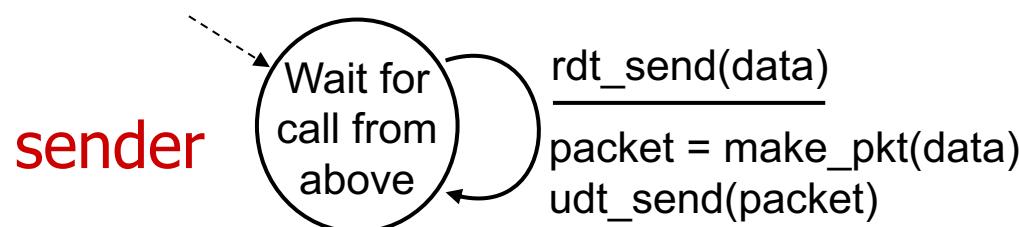

# Channel model: Reliable Channel

- underlying channel perfectly reliable
  - no bit errors
  - no loss of packets

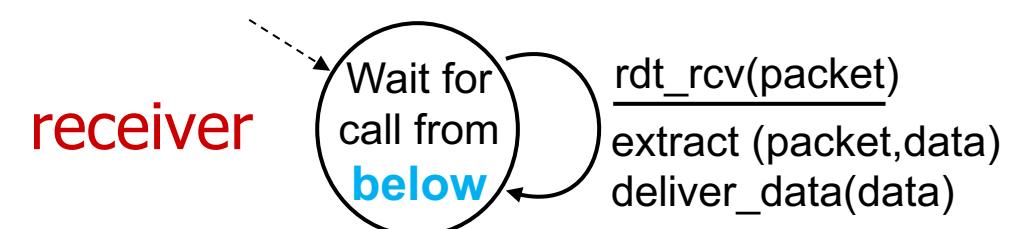

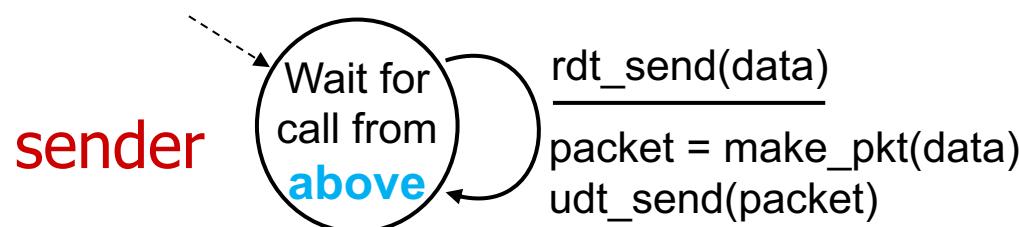

# rdt1.0: reliable transfer over a reliable channel

- *separate* FSMs for sender, receiver:
  - sender sends data into underlying channel
  - receiver reads data from underlying channel

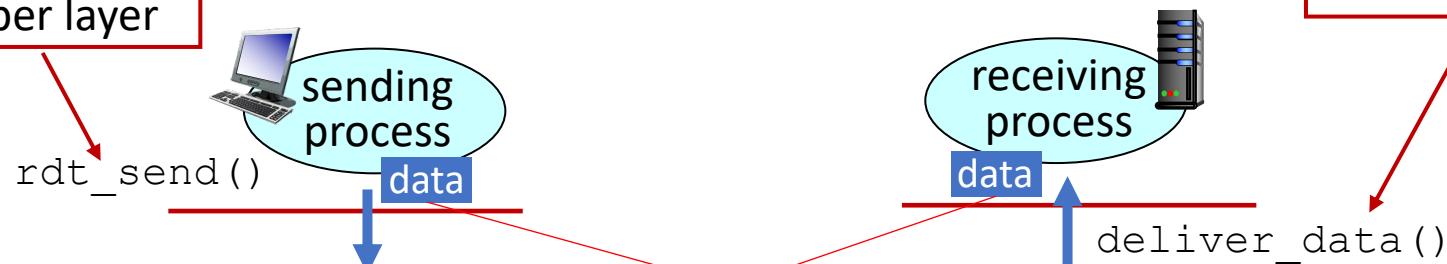

# rdt1.0: reliable transfer over a reliable channel

- *separate* FSMs for sender, receiver:
  - sender sends data into underlying channel
  - receiver reads data from underlying channel

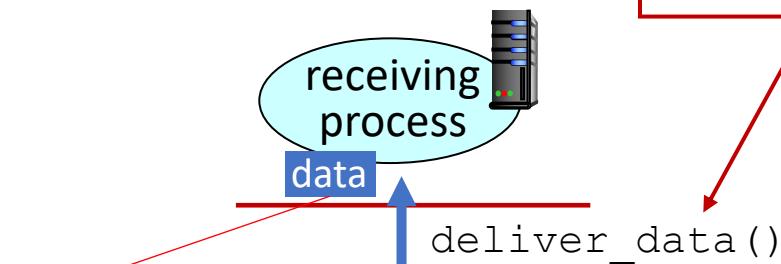

# Reliable data transfer protocol (rdt): interfaces

**rdt\_send():** called from above, (e.g., by app.). Passed data to deliver to receiver upper layer

**deliver\_data():** called by rdt to deliver data to upper layer

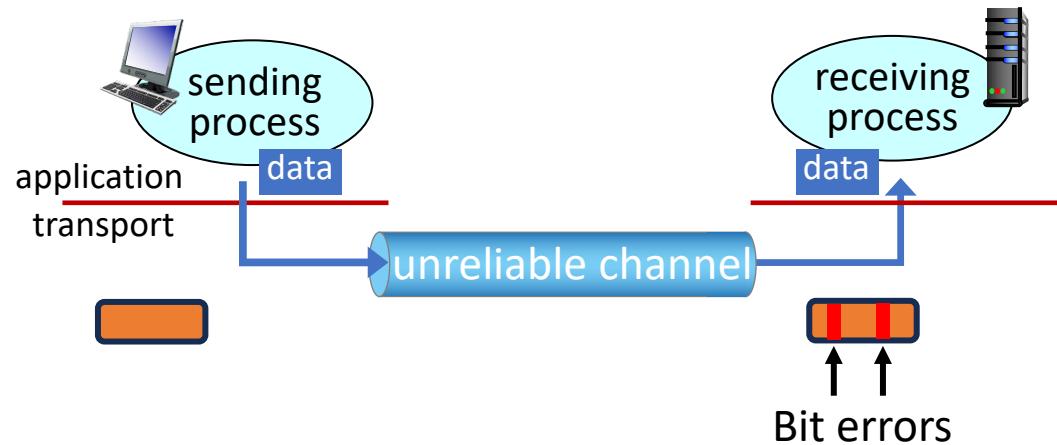

**udt\_send():** called by rdt to transfer packet over unreliable channel to receiver

**rdt\_rcv():** called when packet arrives on receiver side of channel

Bi-directional communication over unreliable channel

# Channel model: channel with bit errors

- underlying channel may flip bits in packet
  - checksum (e.g., Internet checksum) to detect bit errors

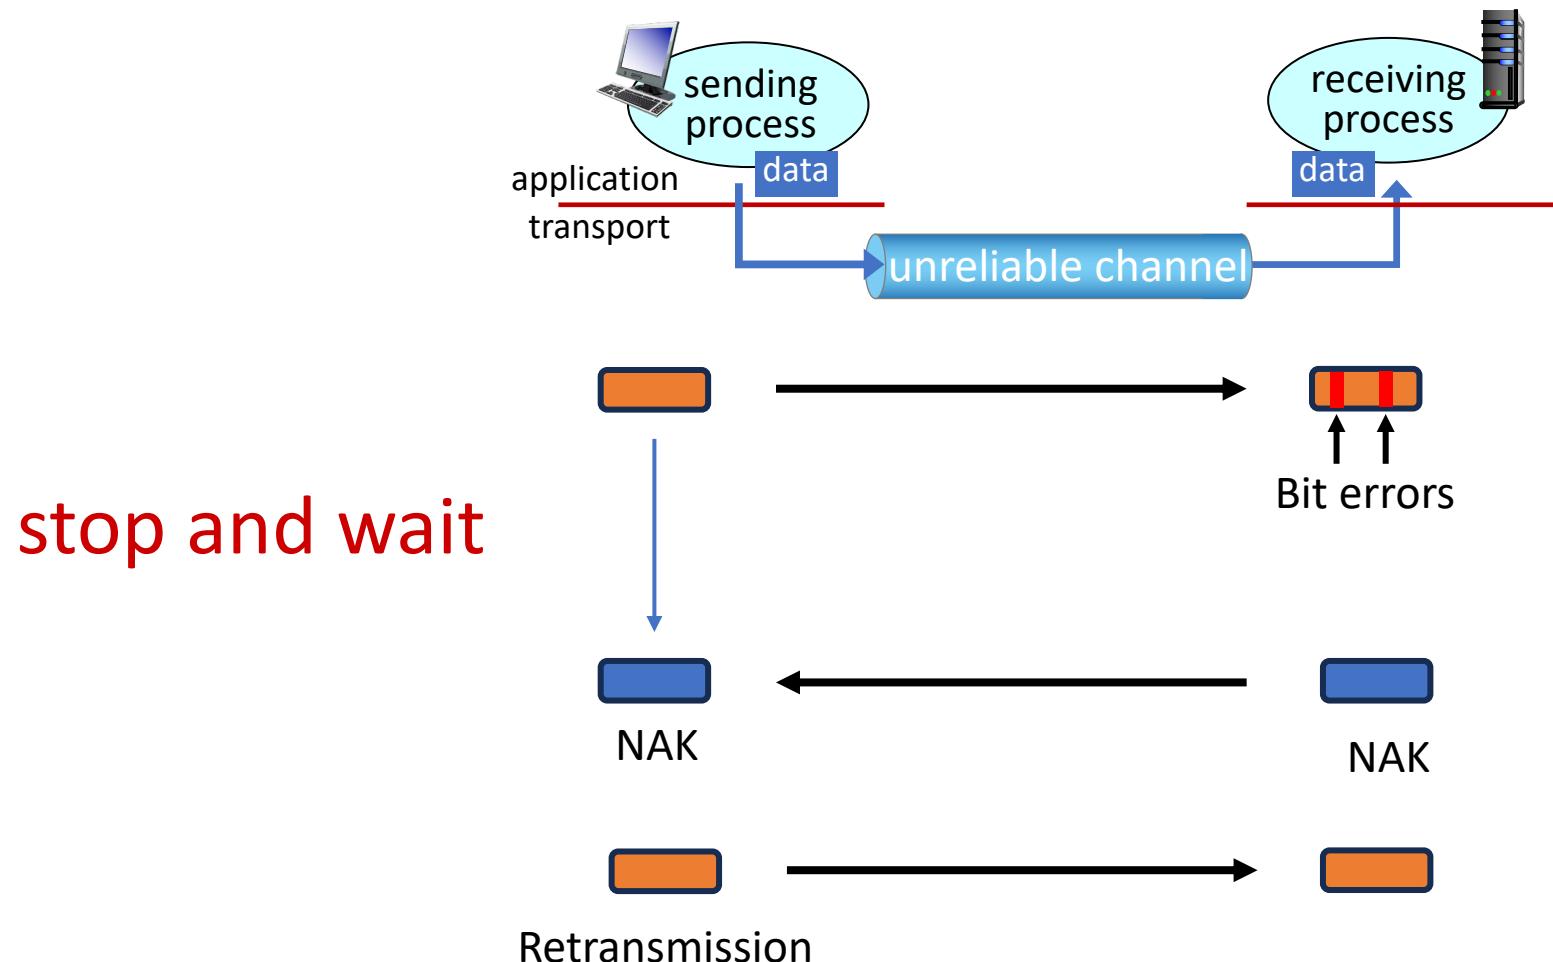

# rdt2.0: channel with bit errors

- underlying channel may flip bits in packet
  - checksum to detect bit errors
- *the question:* how to recover from errors?
  - *acknowledgements (ACKs):* receiver explicitly tells sender that pkt received OK
  - *negative acknowledgements (NAKs):* receiver explicitly tells sender that pkt had errors
  - sender *retransmits* pkt on receipt of NAK

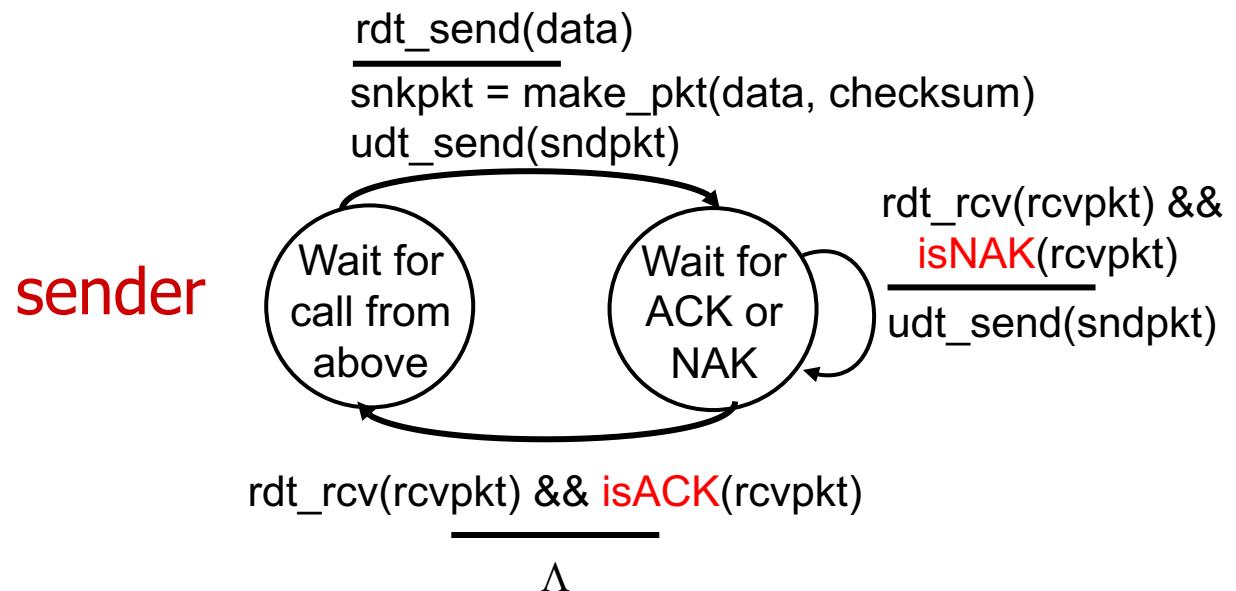

stop and wait

sender sends one packet, then waits for receiver response

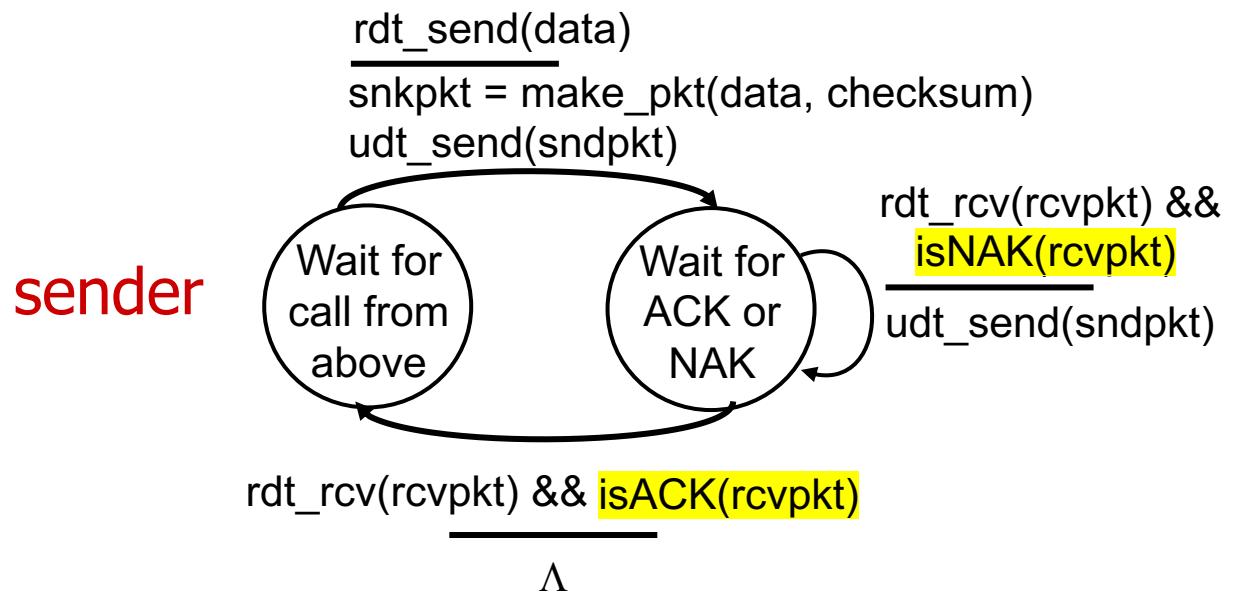

# rdt2.0: channel with bit errors

# rdt2.0: FSM specifications

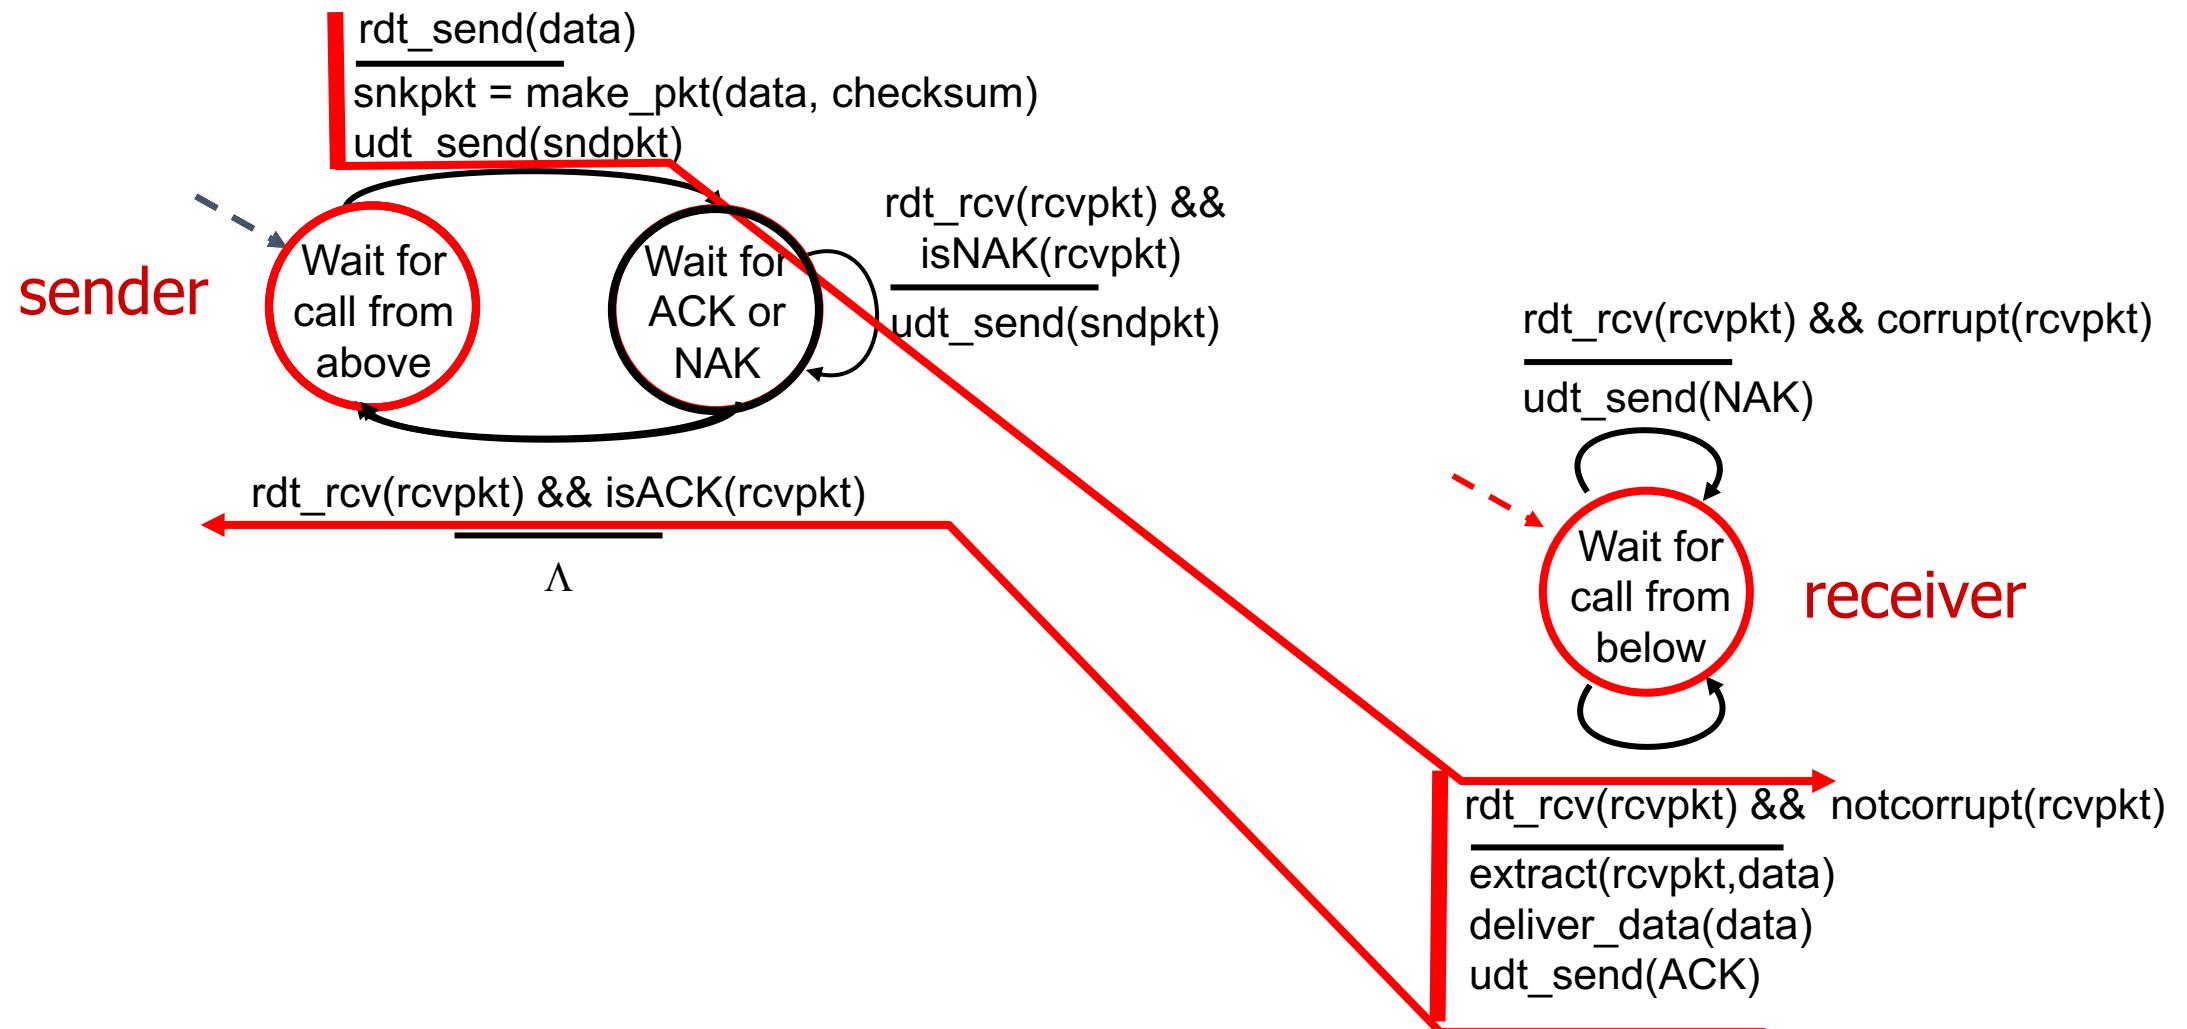

# rdt2.0: FSM specification

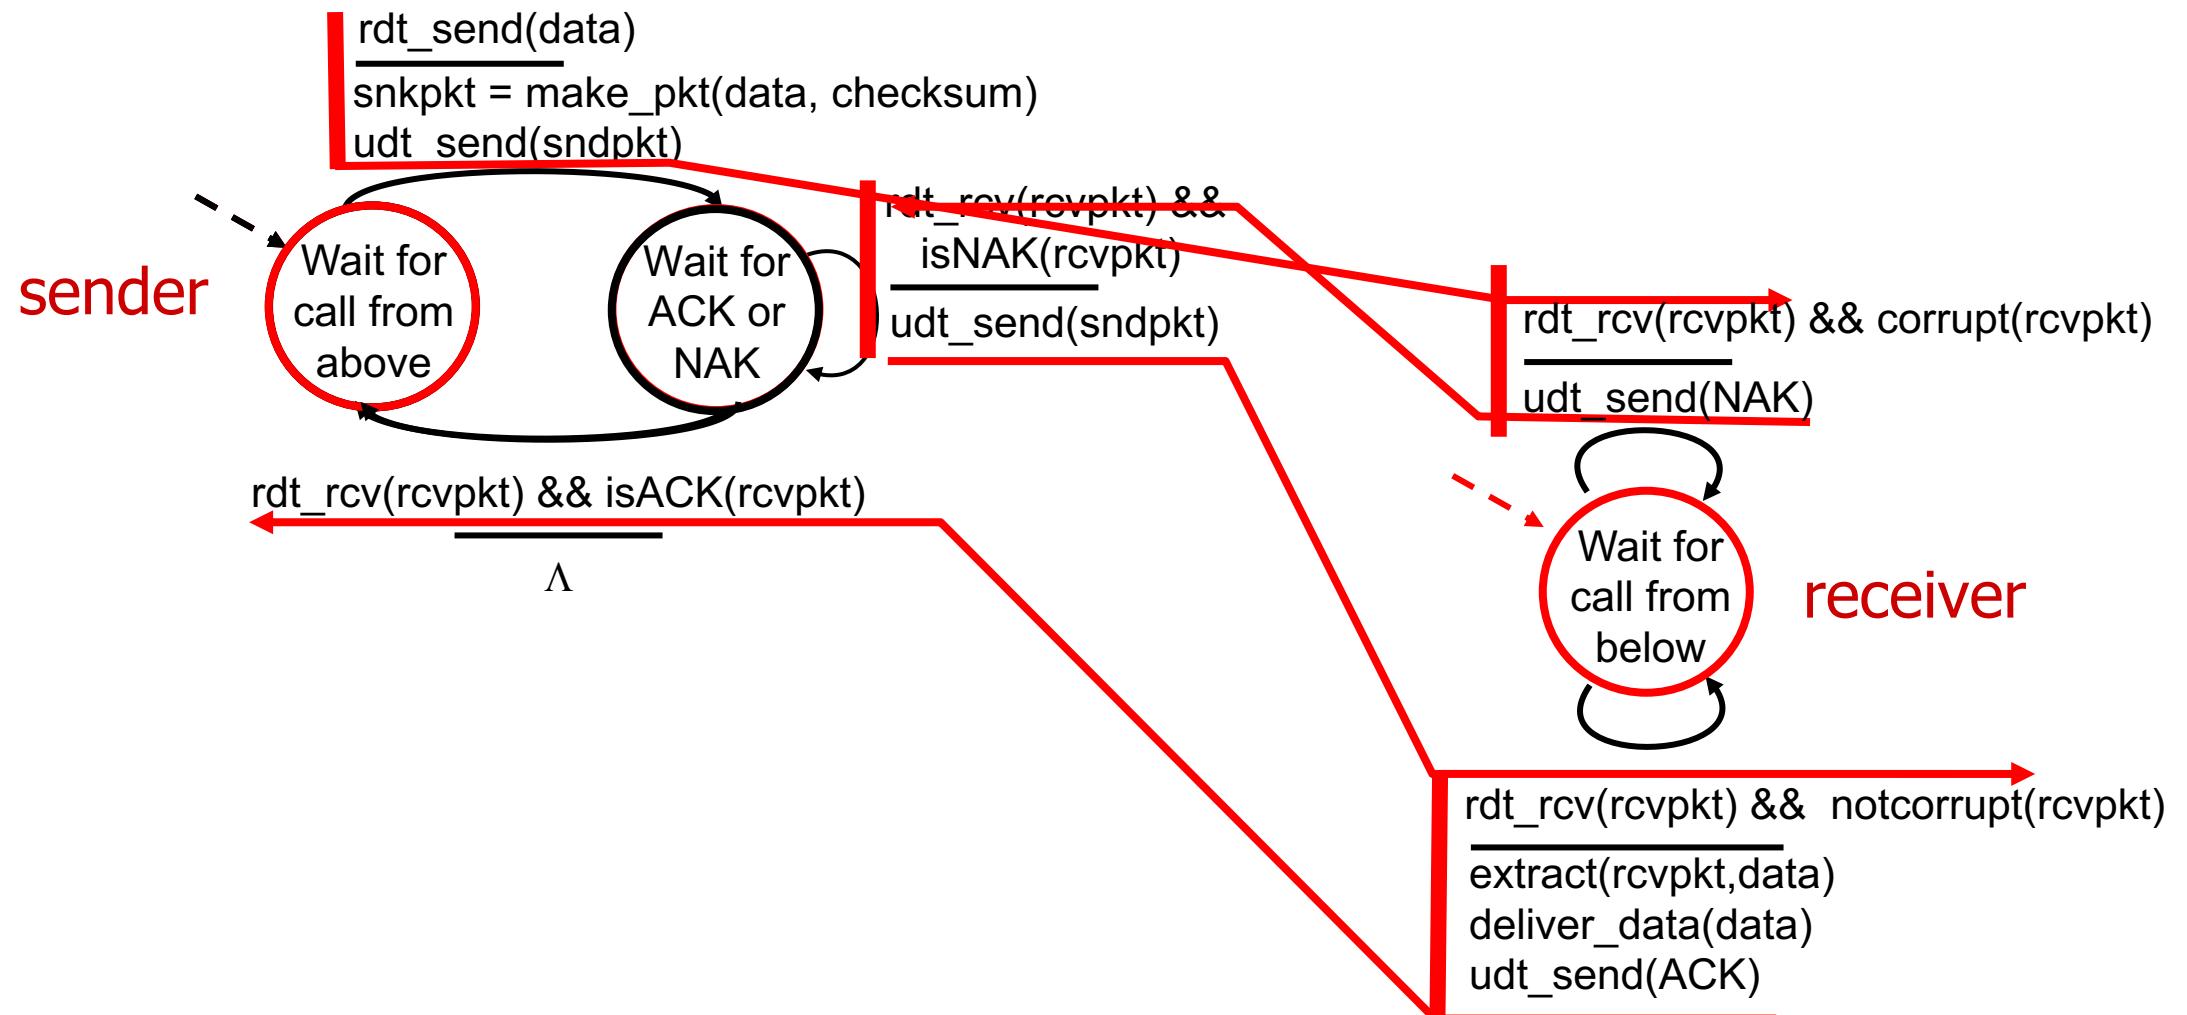

**Note:** “state” of receiver (did the receiver get my message correctly?) isn’t known to sender unless somehow communicated from receiver to sender

- that’s why we need a protocol!

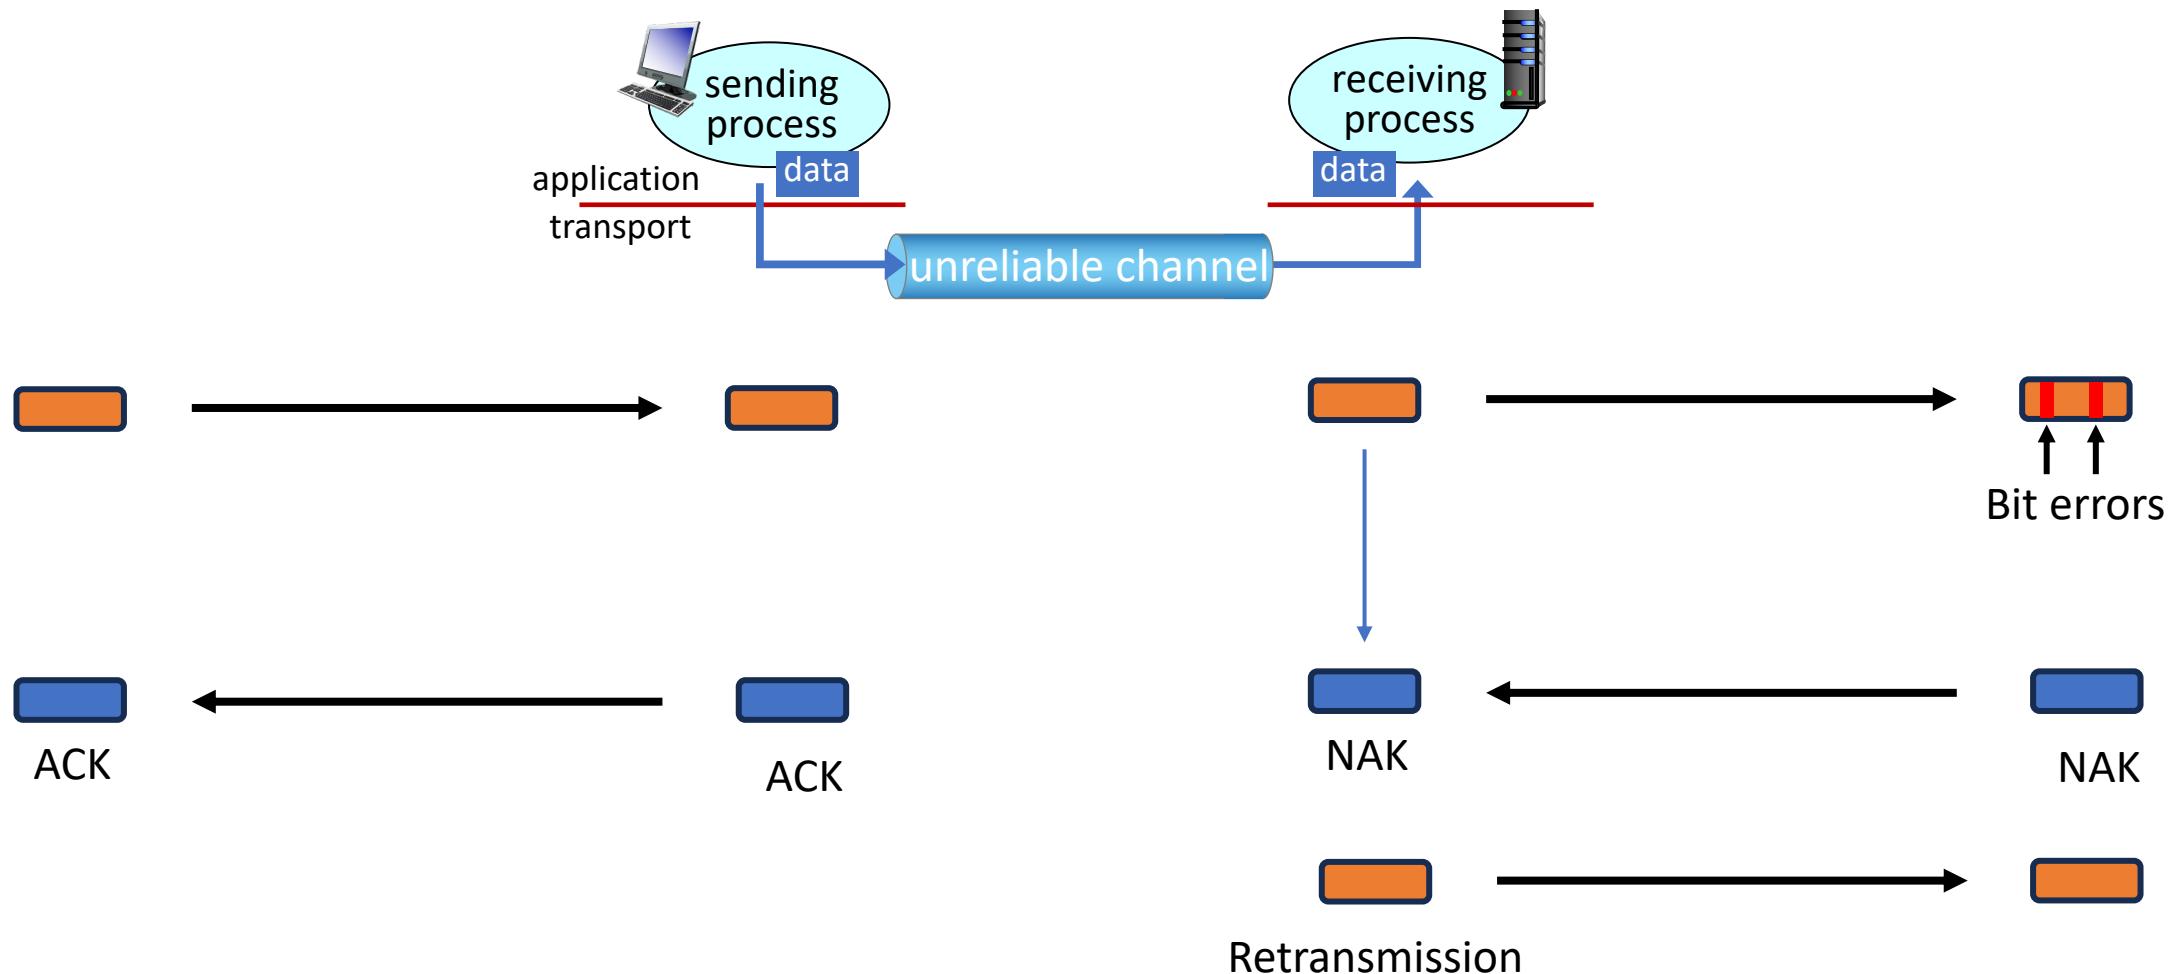

# rdt2.0: operation with no errors

# rdt2.0: corrupted packet scenario

# rdt2.0: no errors VS. corrupted packets

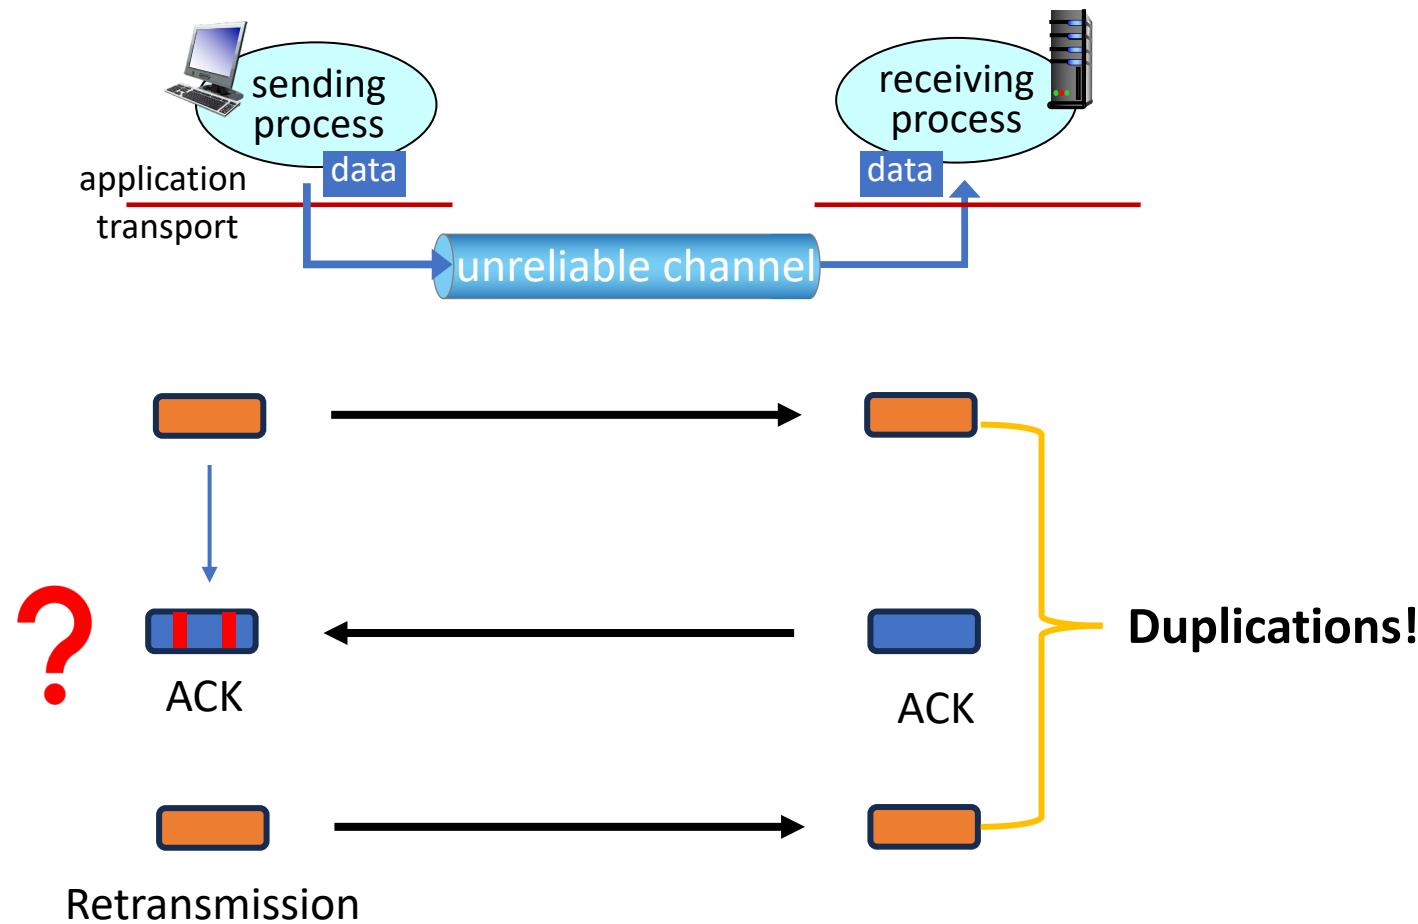

# rdt2.0 has a fatal flaw!

what happens if ACK/NAK corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

# rdt2.0: corrupted ACK

# rdt2.0 has a fatal flaw!

what happens if ACK/NAK corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

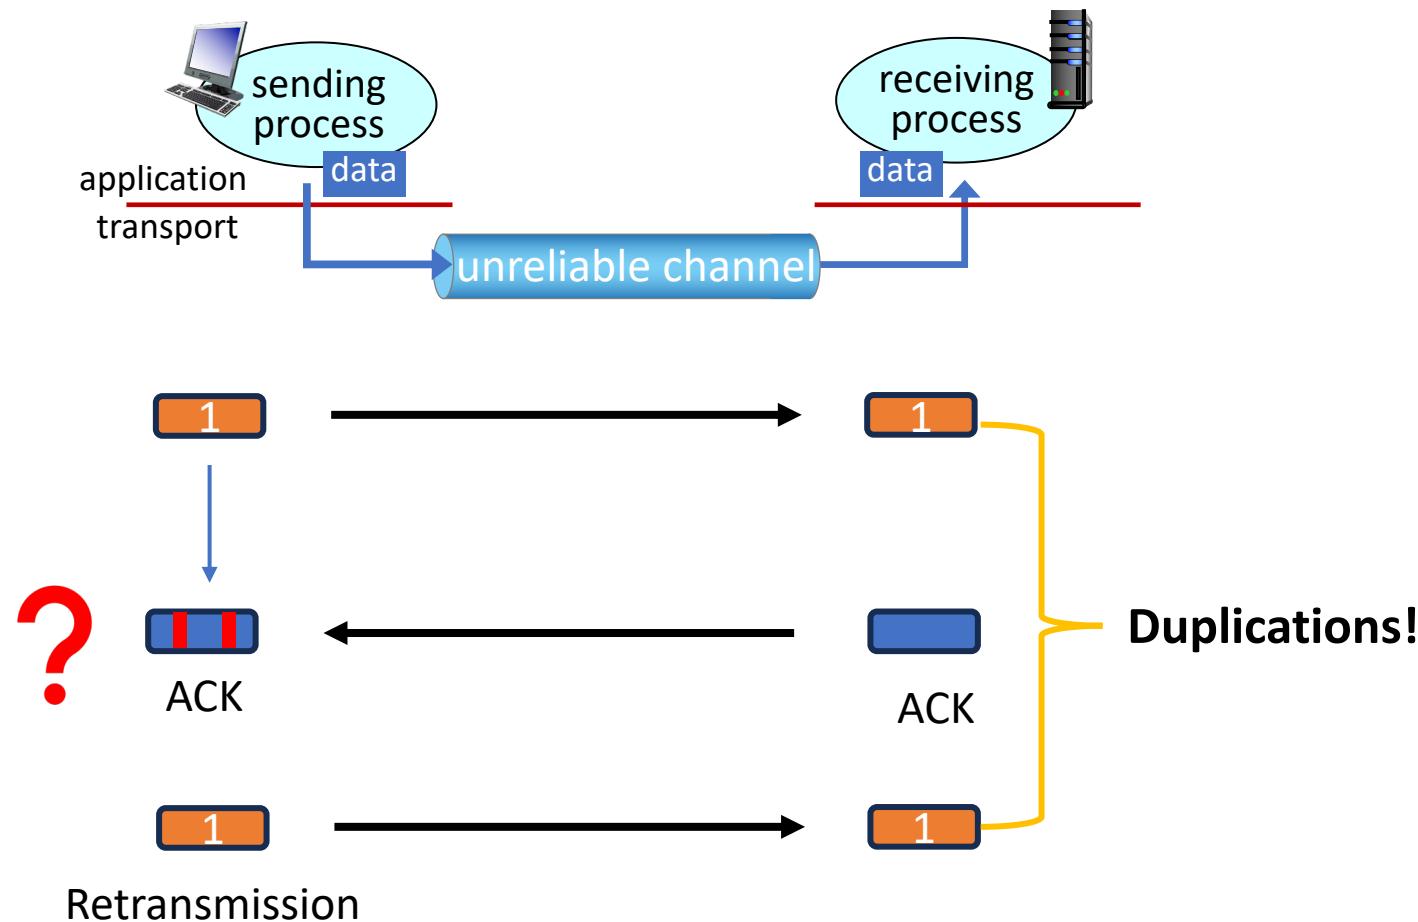

handling duplicates:

- sender retransmits current pkt if ACK/NAK corrupted
- sender adds *sequence number* to each pkt
- receiver discards (doesn't deliver up) duplicate pkt

stop and wait

sender sends one packet, then waits for receiver response

# rdt2.0: corrupted ACK

# rdt2.1: summary

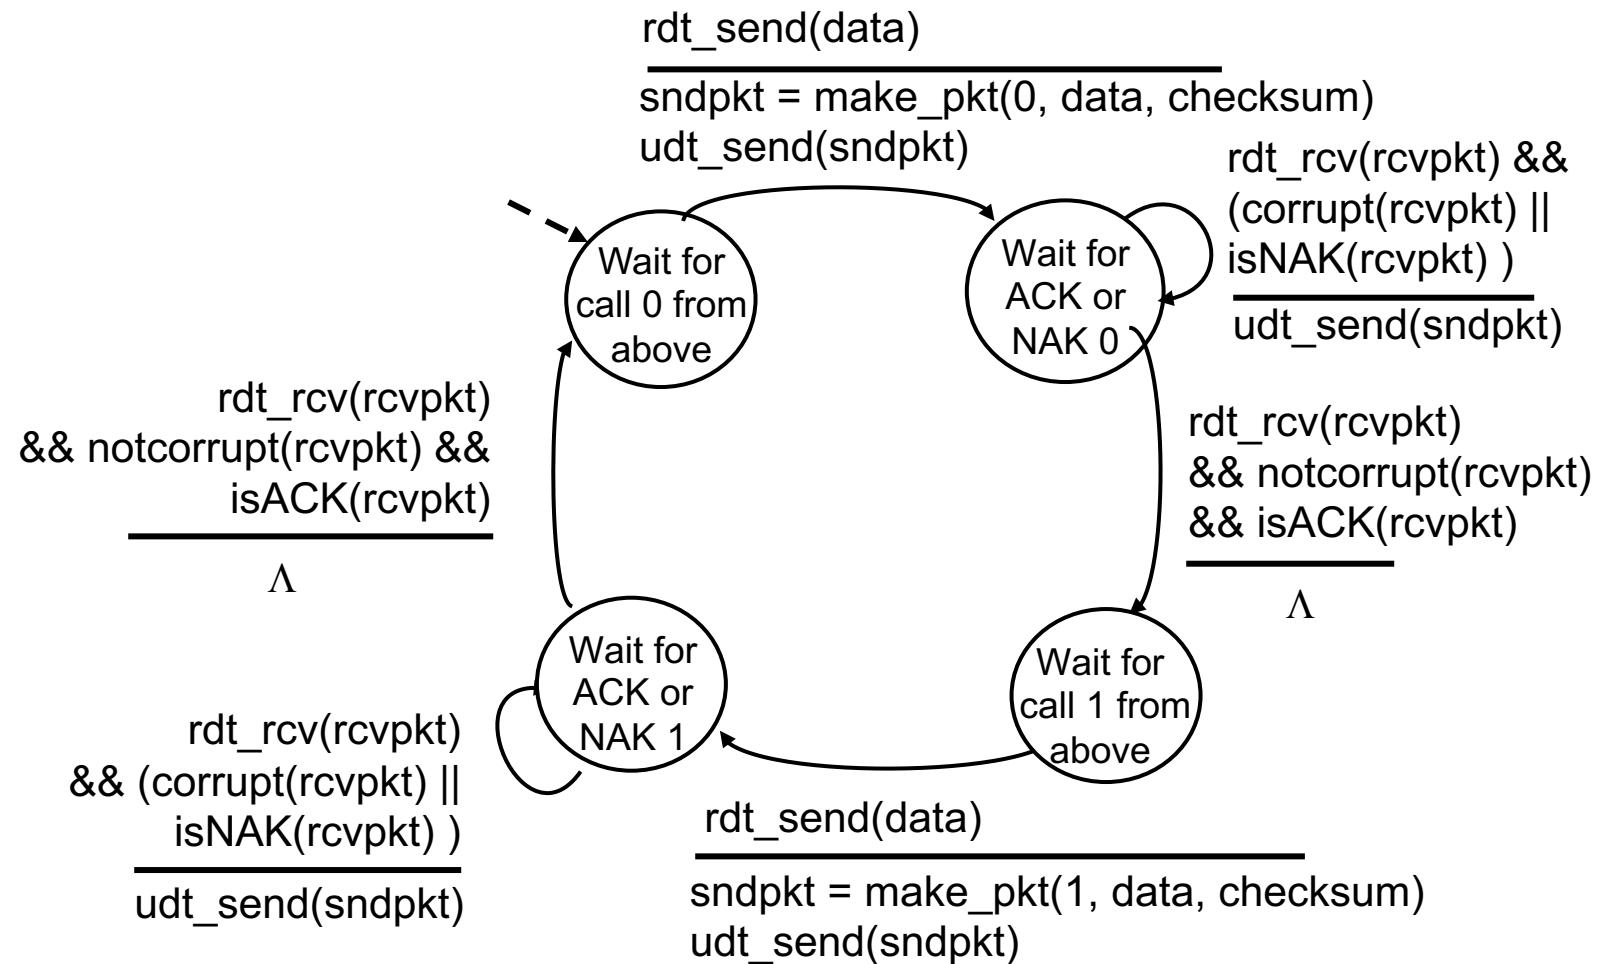

## sender:

- seq # added to pkt
- two seq. #s (0,1) will suffice.  
Why?
- must check if received ACK/NAK corrupted
- twice as many states
  - state must “remember” whether “expected” pkt should have seq # of 0 or 1

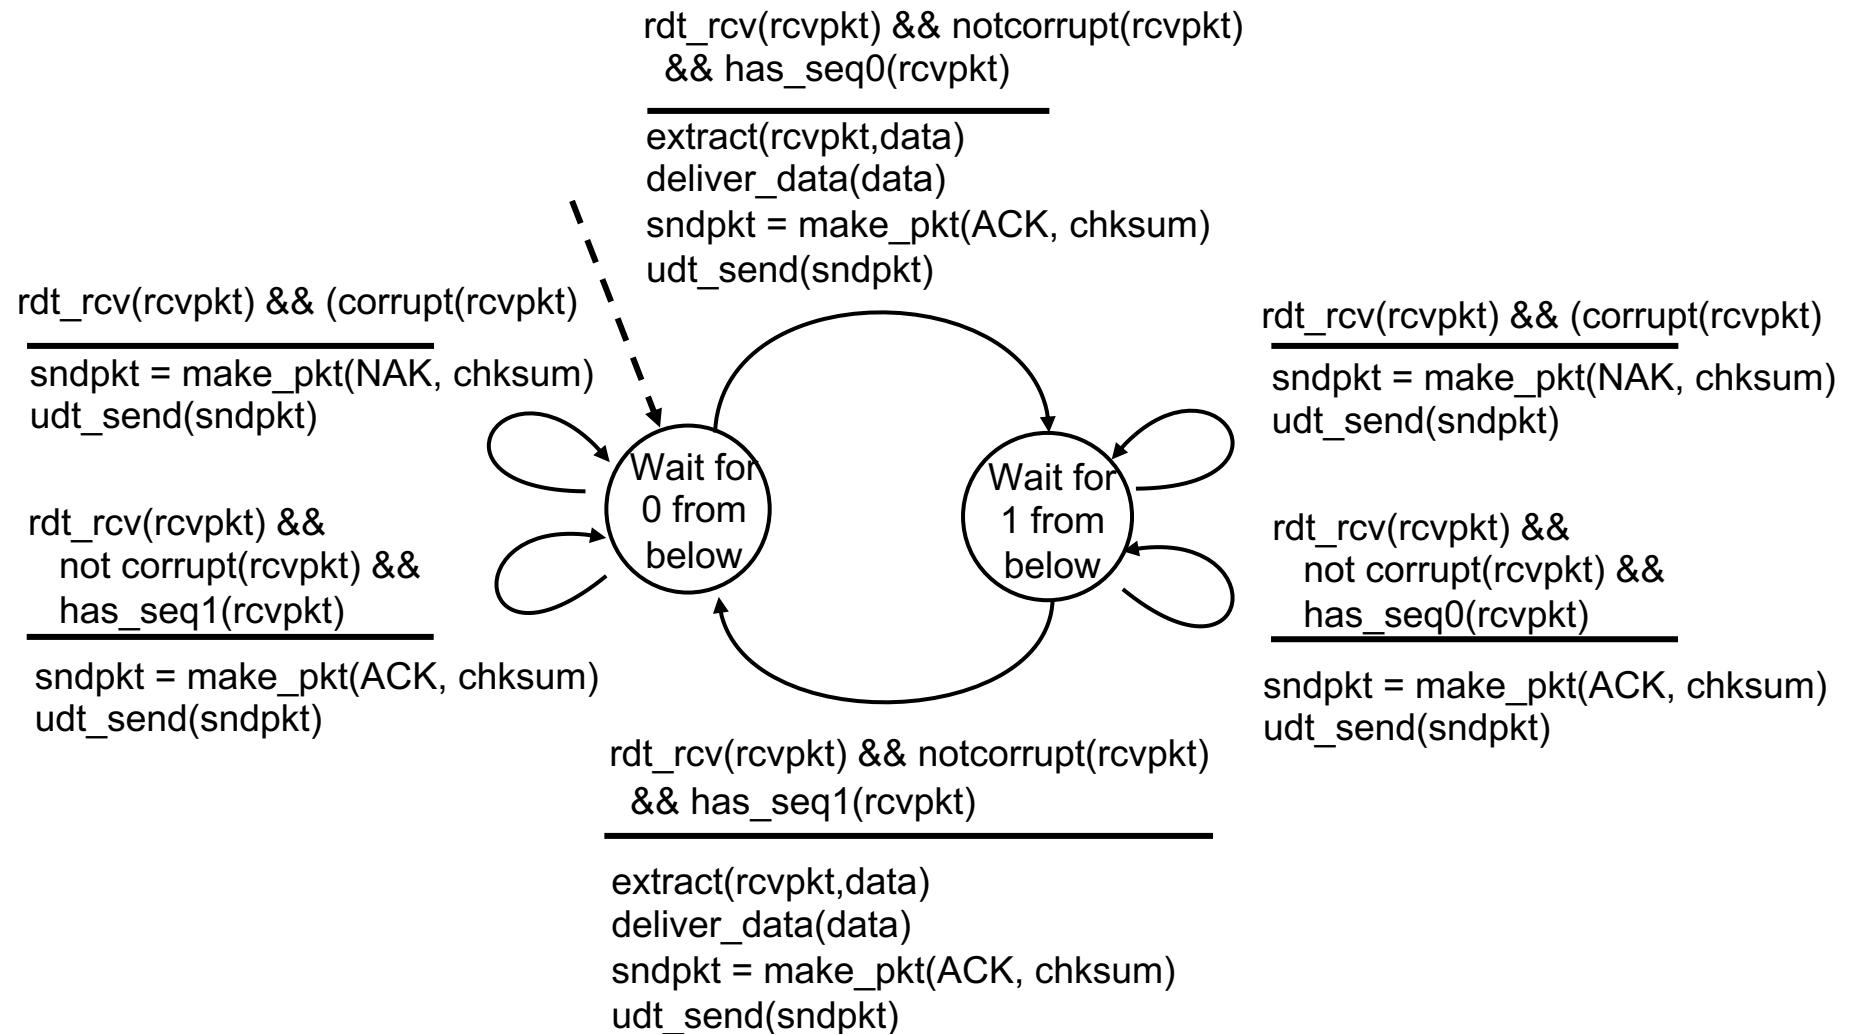

## receiver:

- must check if received packet is duplicate
  - state indicates whether 0 or 1 is expected pkt seq #
- note: receiver can *not* know if its last ACK/NAK received OK at sender

# rdt2.1: sender, handling garbled ACK/NAKs

# rdt2.1: receiver, handling garbled ACK/NAKs

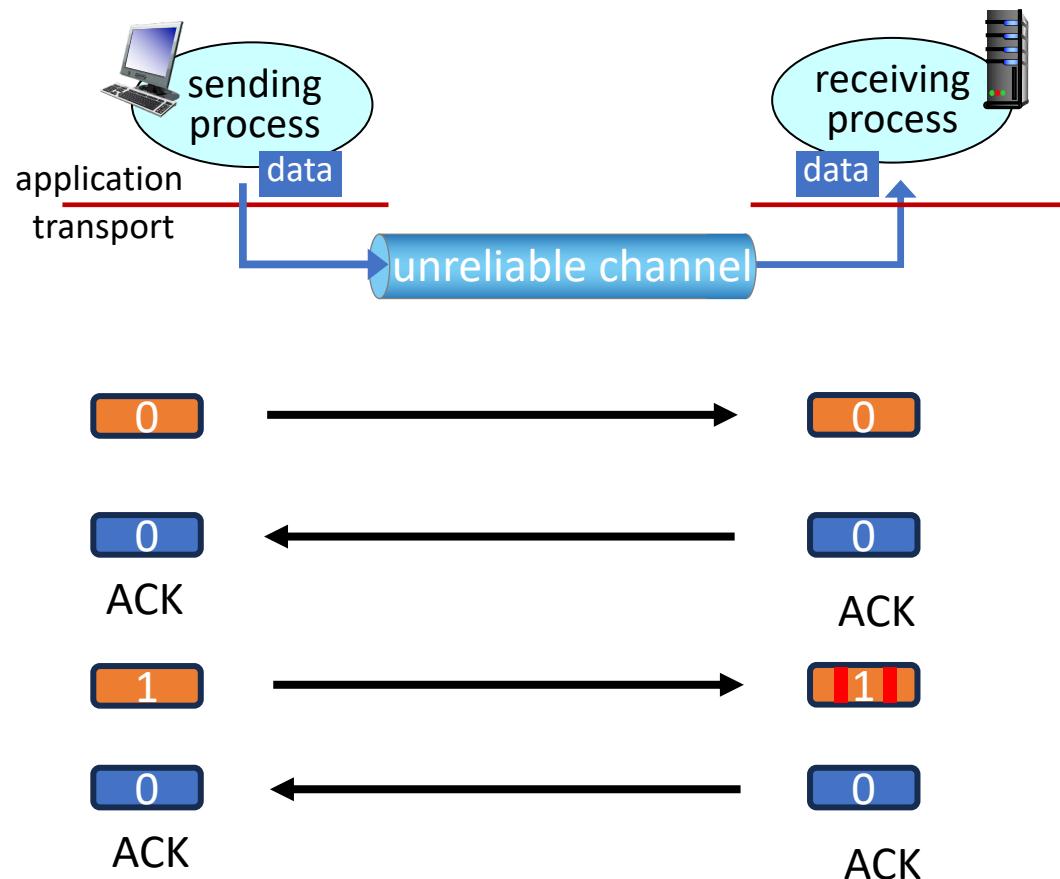

# rdt2.2: a NAK-free protocol

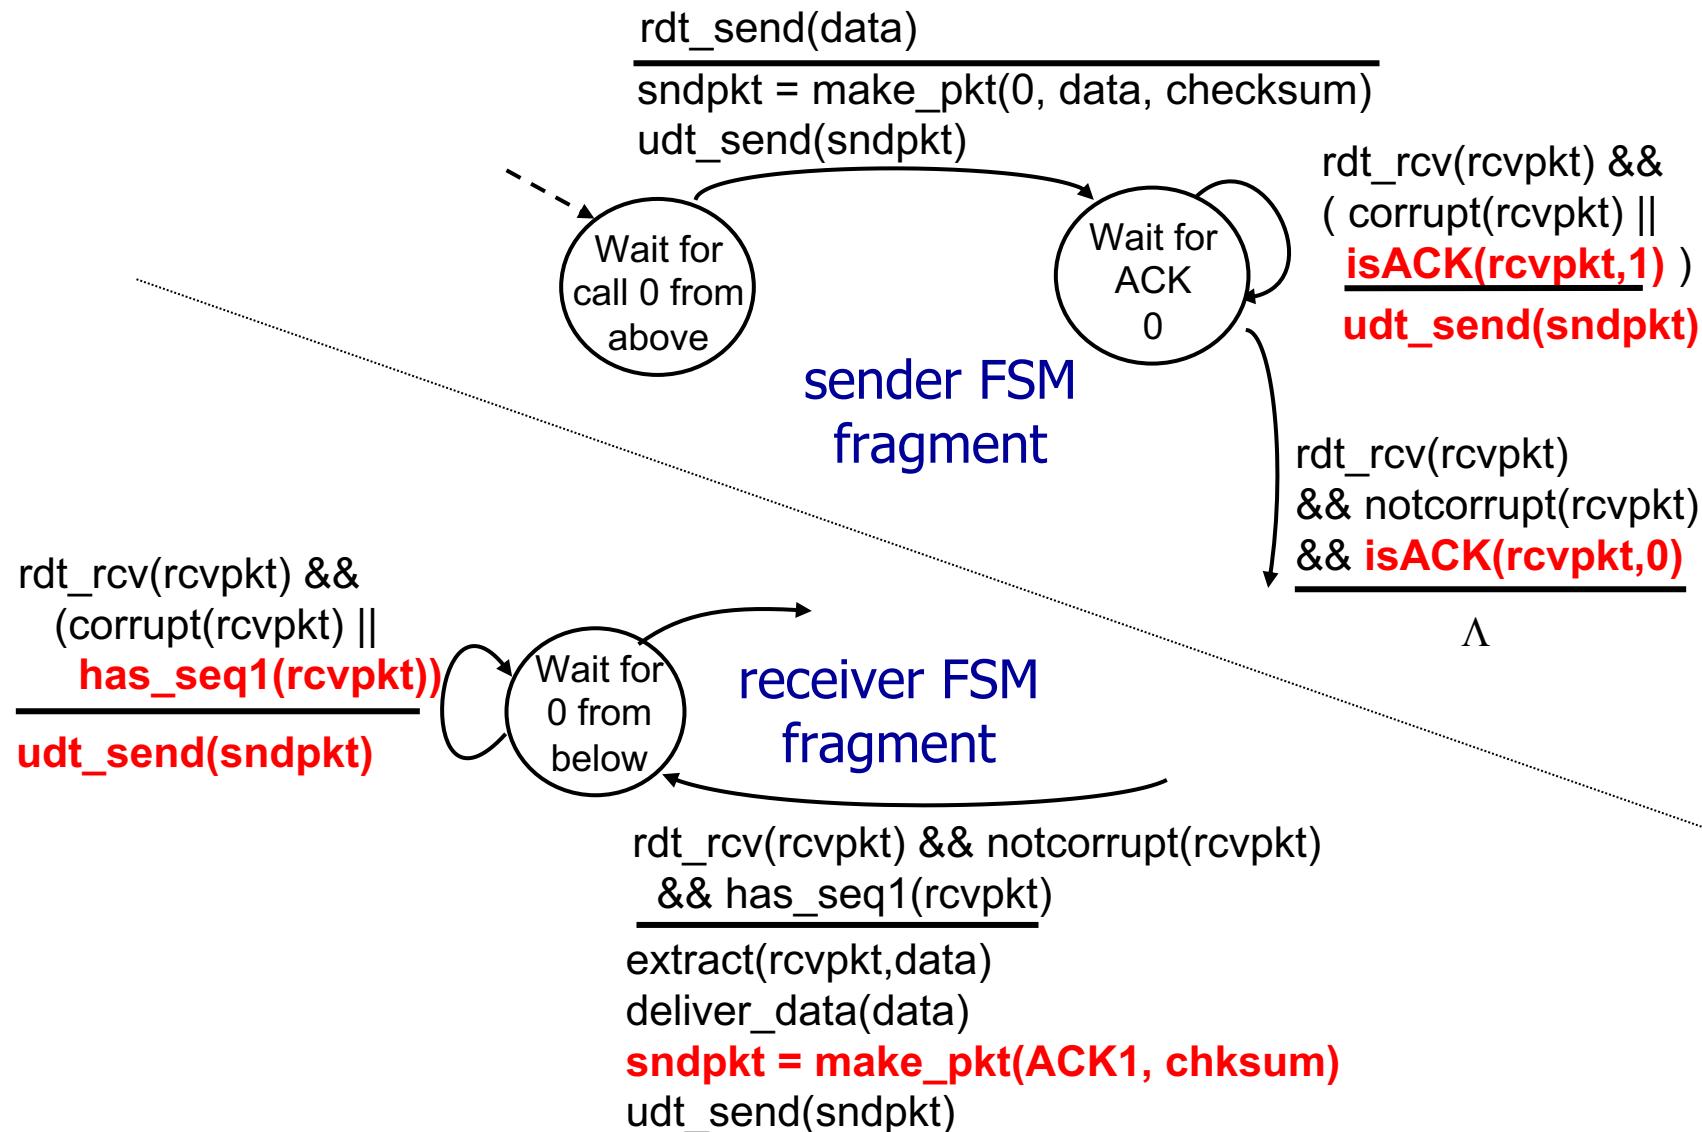

- same functionality as rdt2.1, using ACKs only
- instead of NAK, receiver sends ACK for last pkt received OK
  - receiver must *explicitly* include seq # of pkt being ACKed
- duplicate ACK at sender results in same action as NAK:  
*retransmit current pkt*

As we will see, TCP uses this approach to be NAK-free

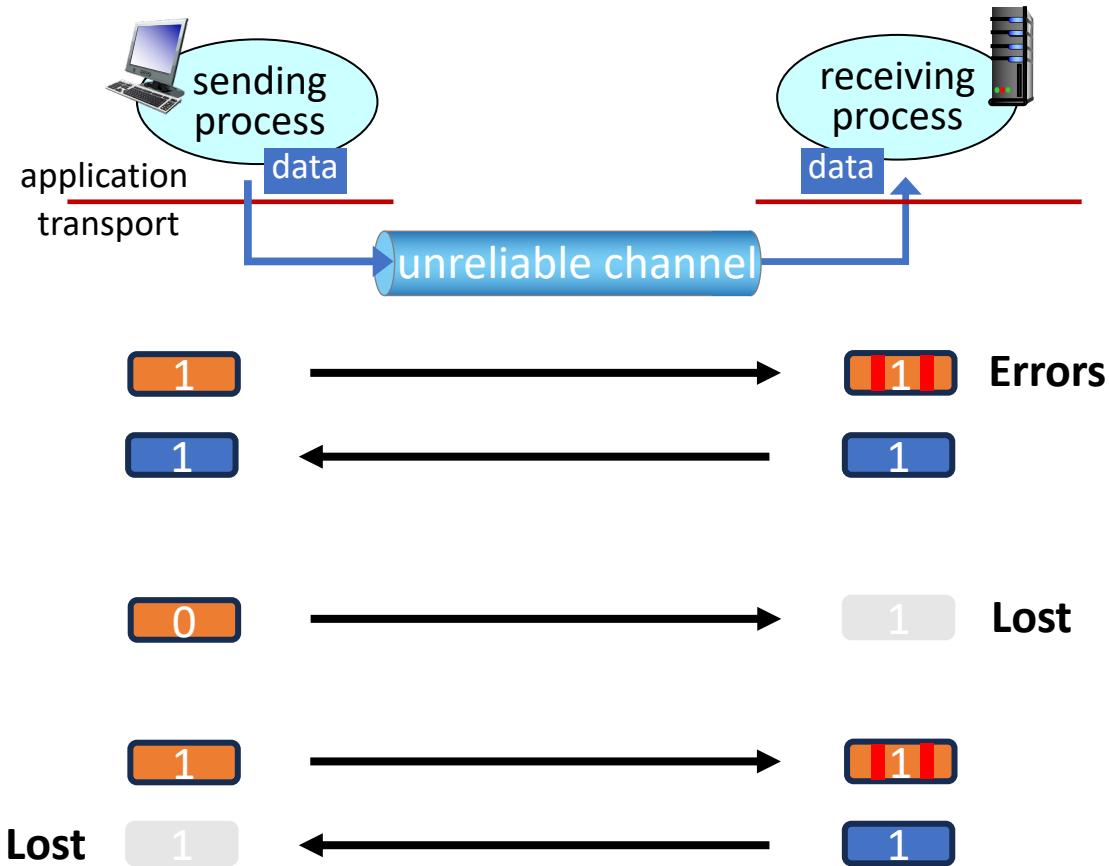

# rdt2.0: NAK-free

# rdt2.2: sender, receiver fragments

# rdt3.0: channels with errors *and* loss

# rdt3.0: channels with errors *and* loss

**New channel assumption:** underlying channel can also *lose* packets (data, ACKs)

- checksum, sequence #s, ACKs, retransmissions will be of help ...  
but not quite enough

**Q:** How do *humans* handle lost sender-to-receiver words in conversation?

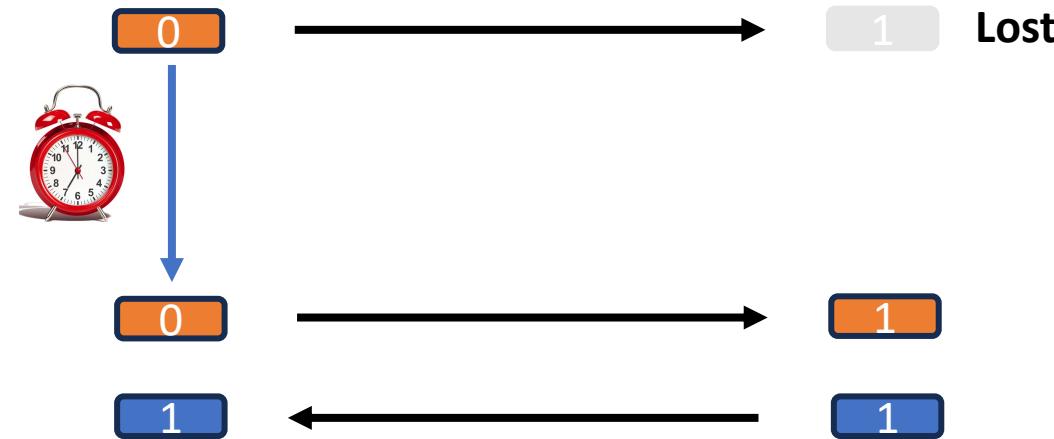

# rdt3.0: channels with errors *and* loss

**Approach:** sender waits “reasonable” amount of time for ACK

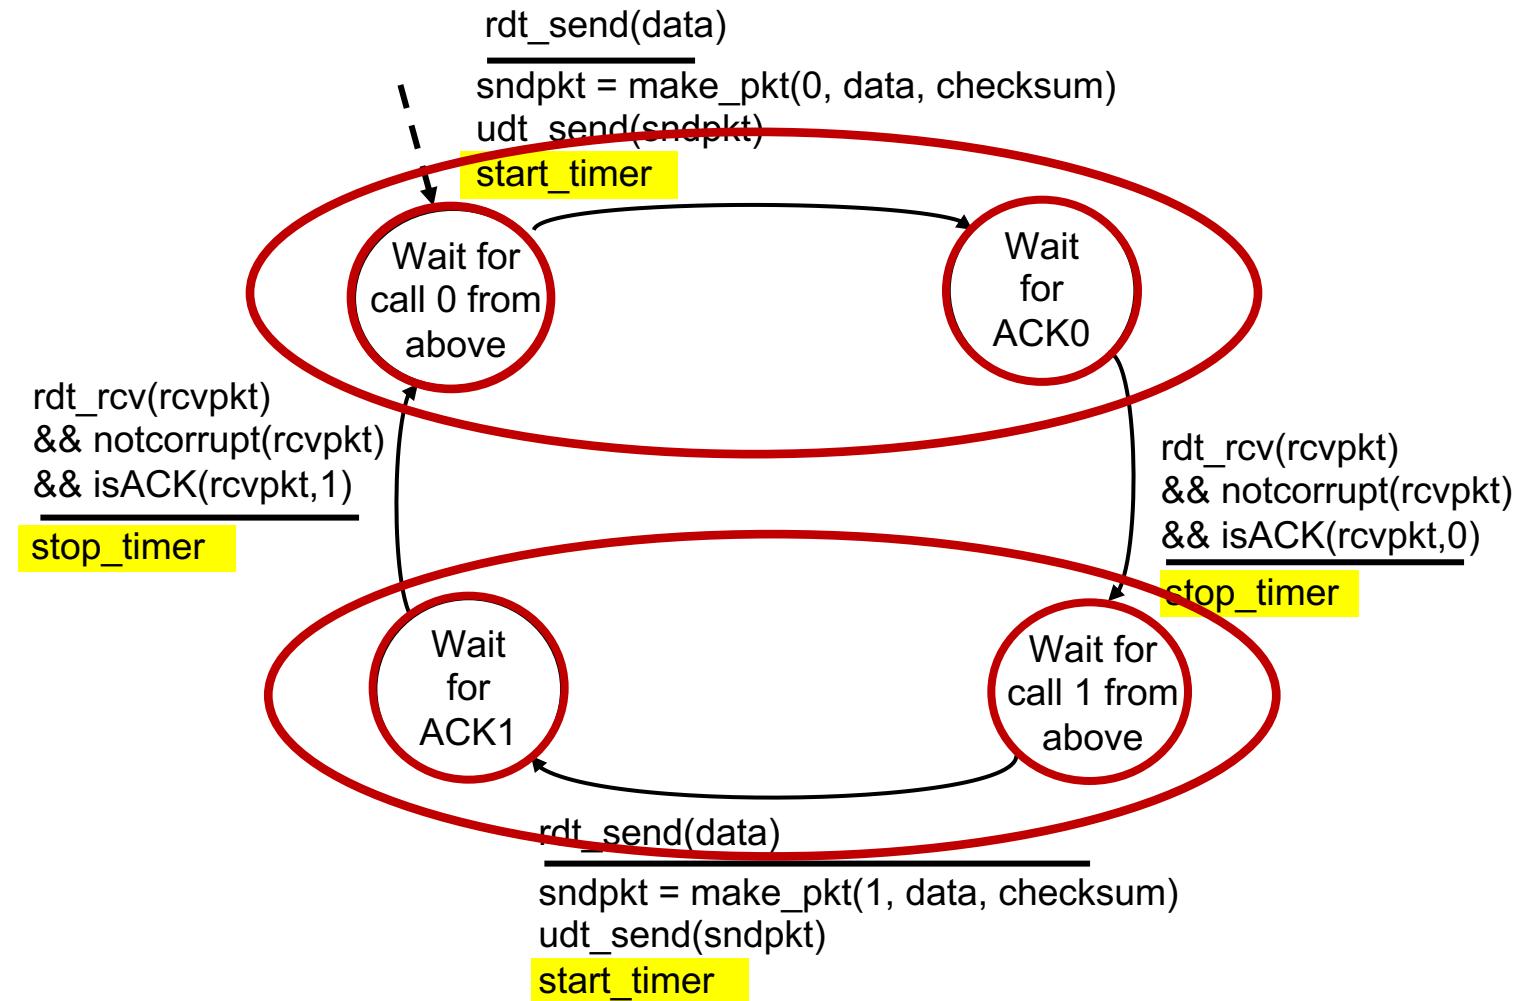

- retransmits if no ACK received in this time
- if pkt (or ACK) just delayed (not lost):
  - retransmission will be duplicate, but seq #s already handles this!
  - receiver must specify seq # of packet being ACKed
- use countdown timer to interrupt after “reasonable” amount of time

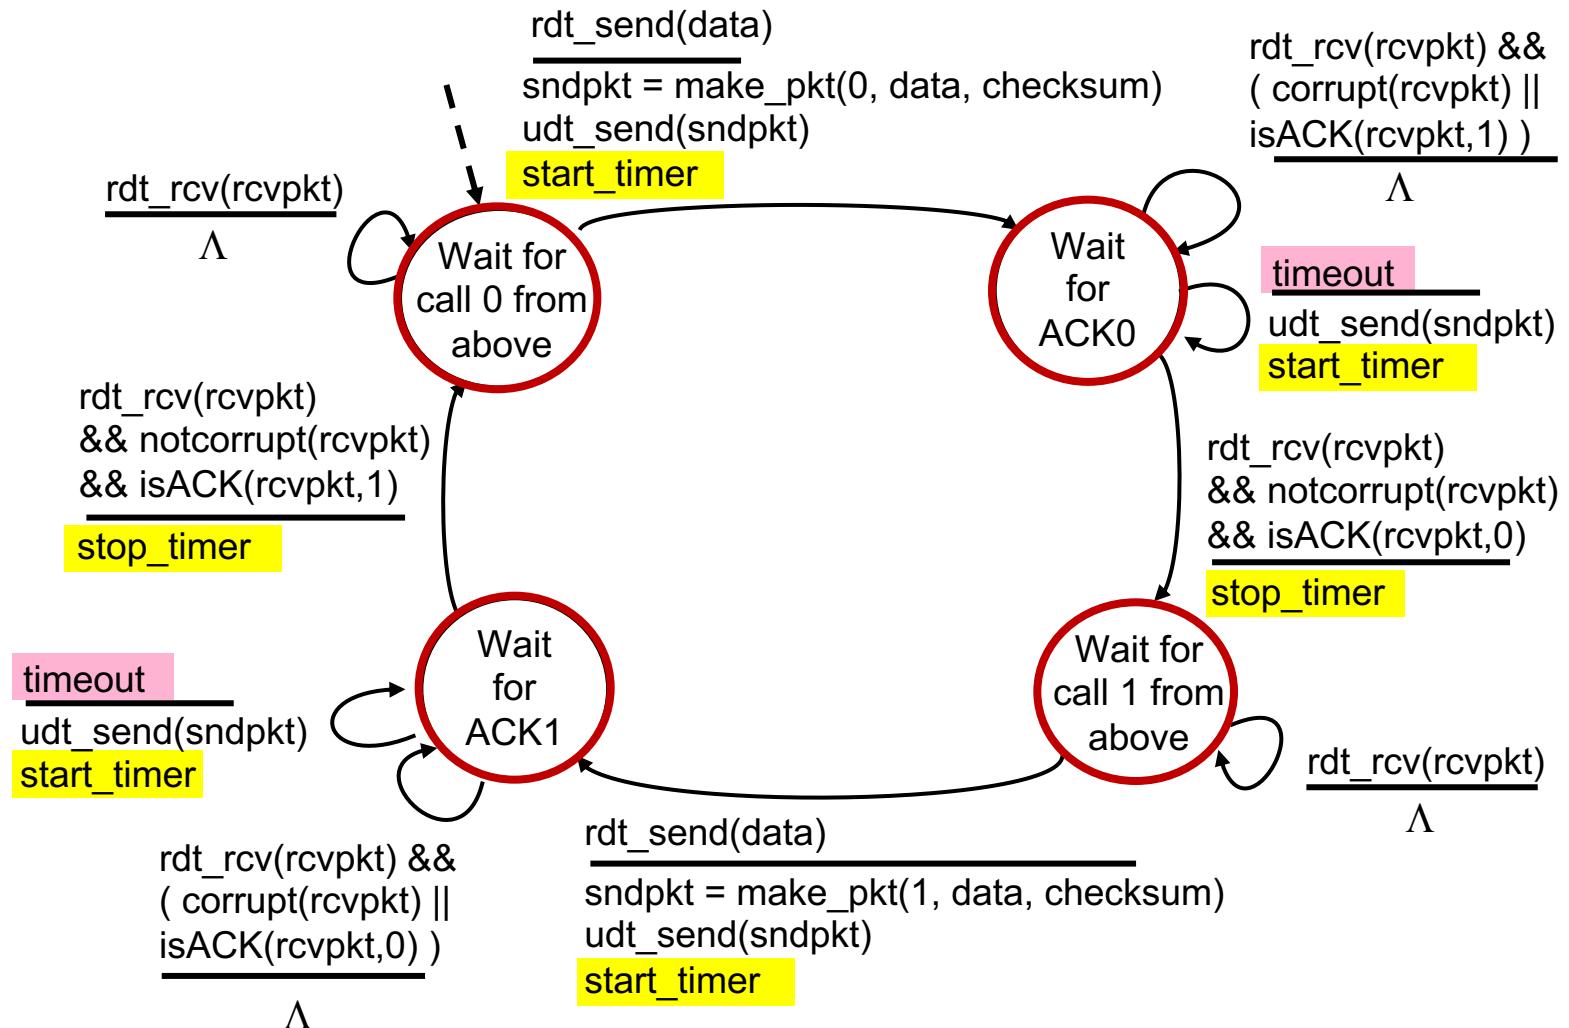

# rdt3.0: channels with errors and loss

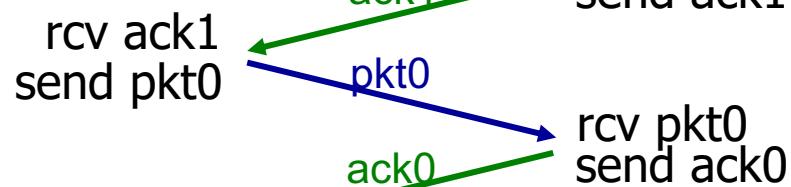

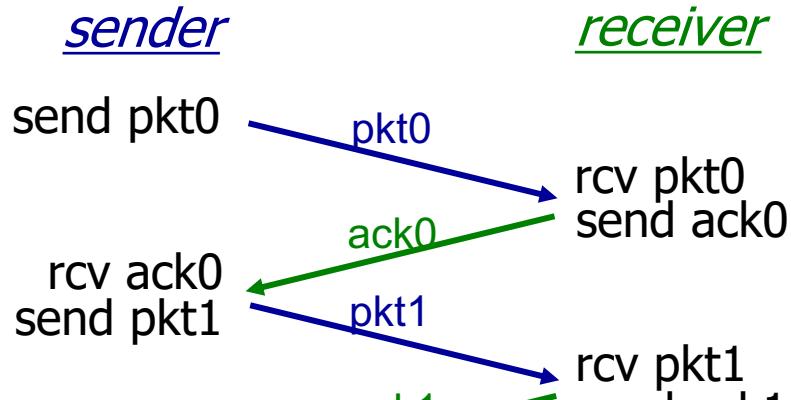

# rdt3.0 sender

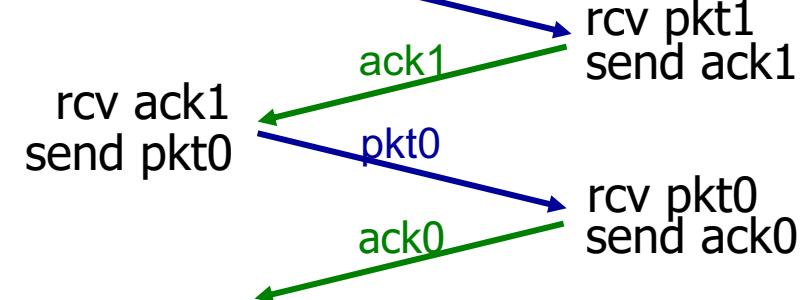

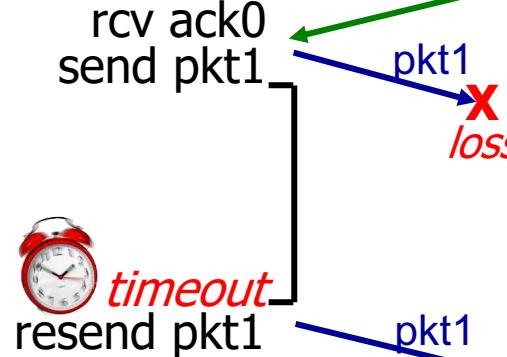

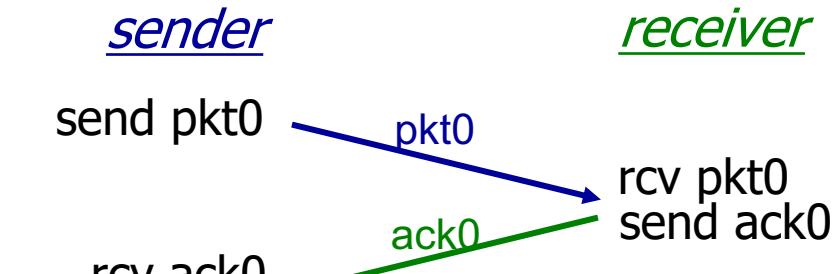

# rdt3.0 sender

# rdt3.0 in action

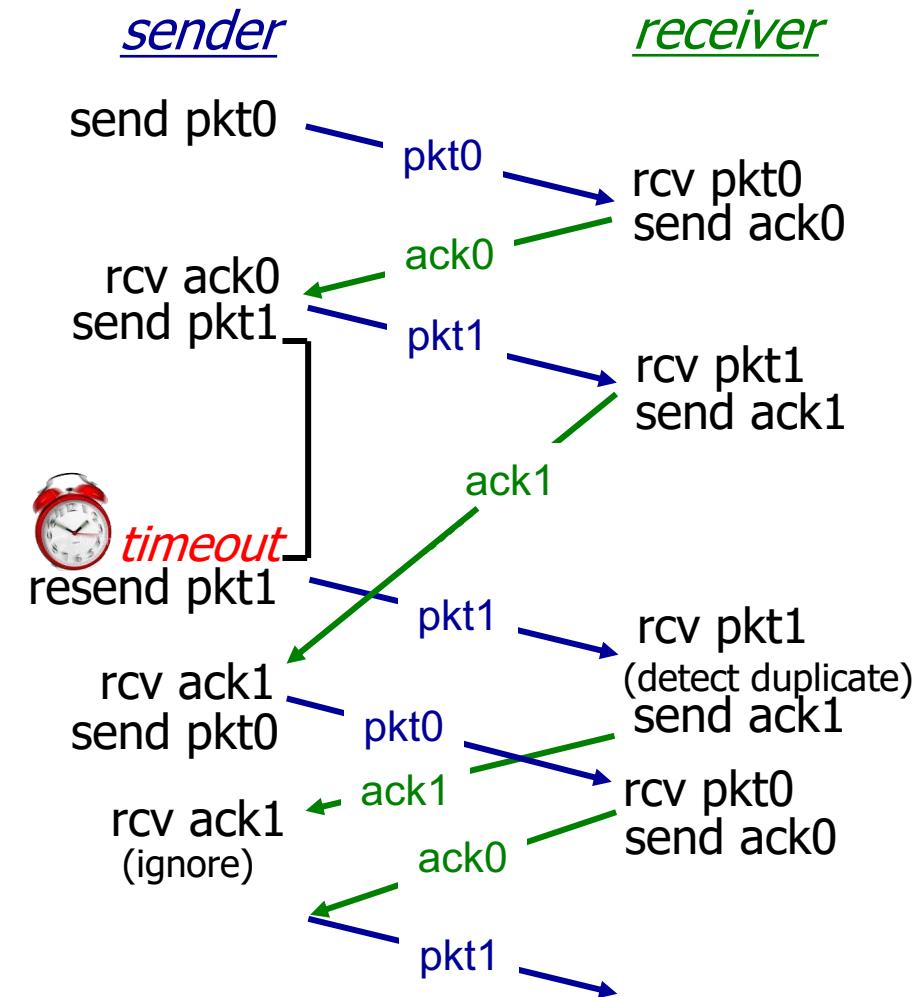

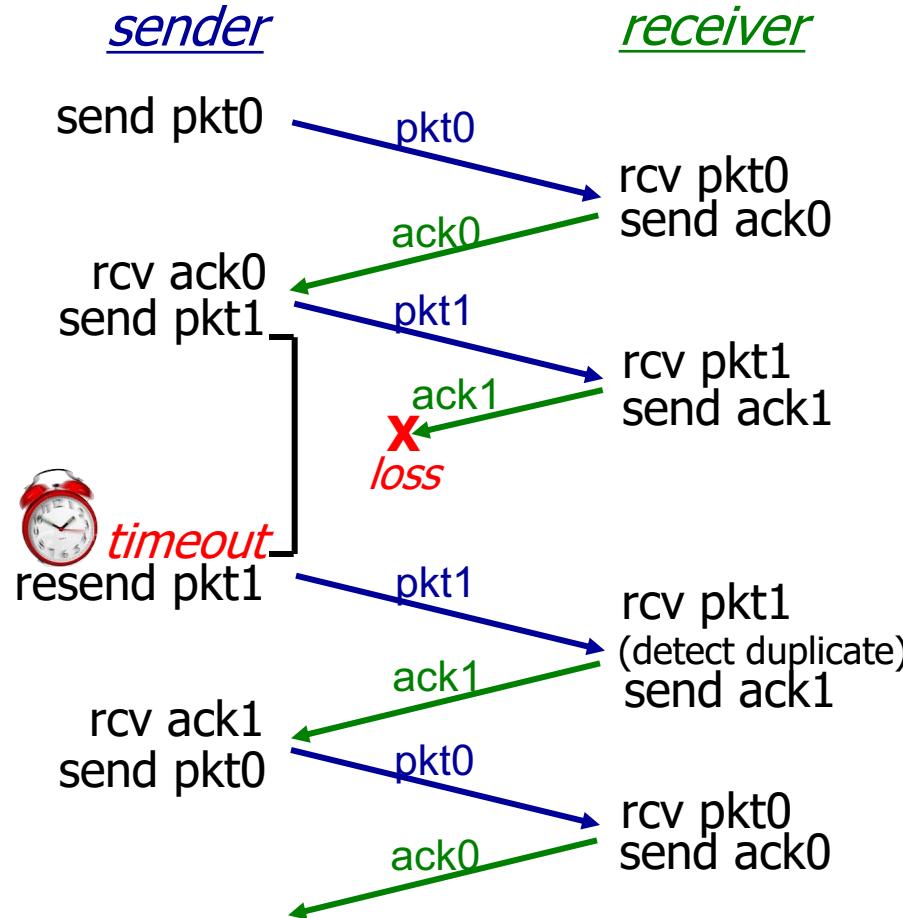

(a) no loss

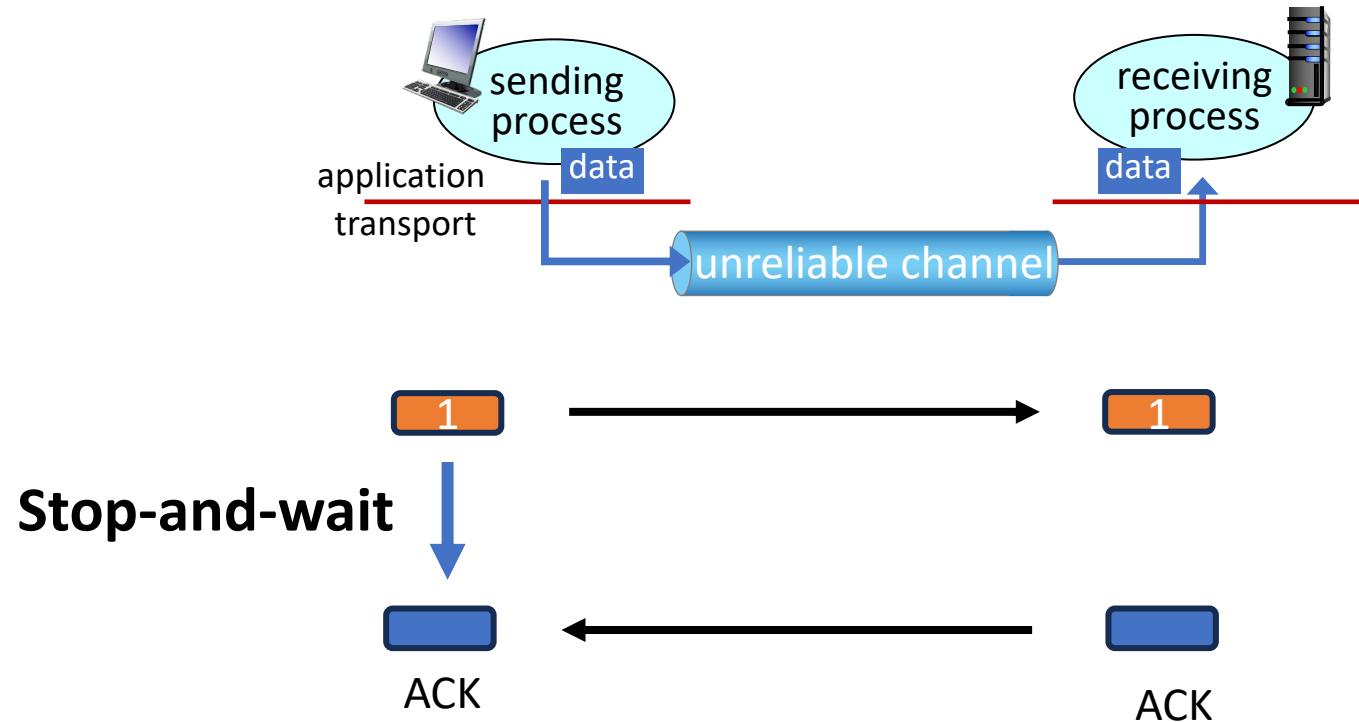

(b) packet loss

# rdt3.0 in action

# rdt3.0: Efficiency

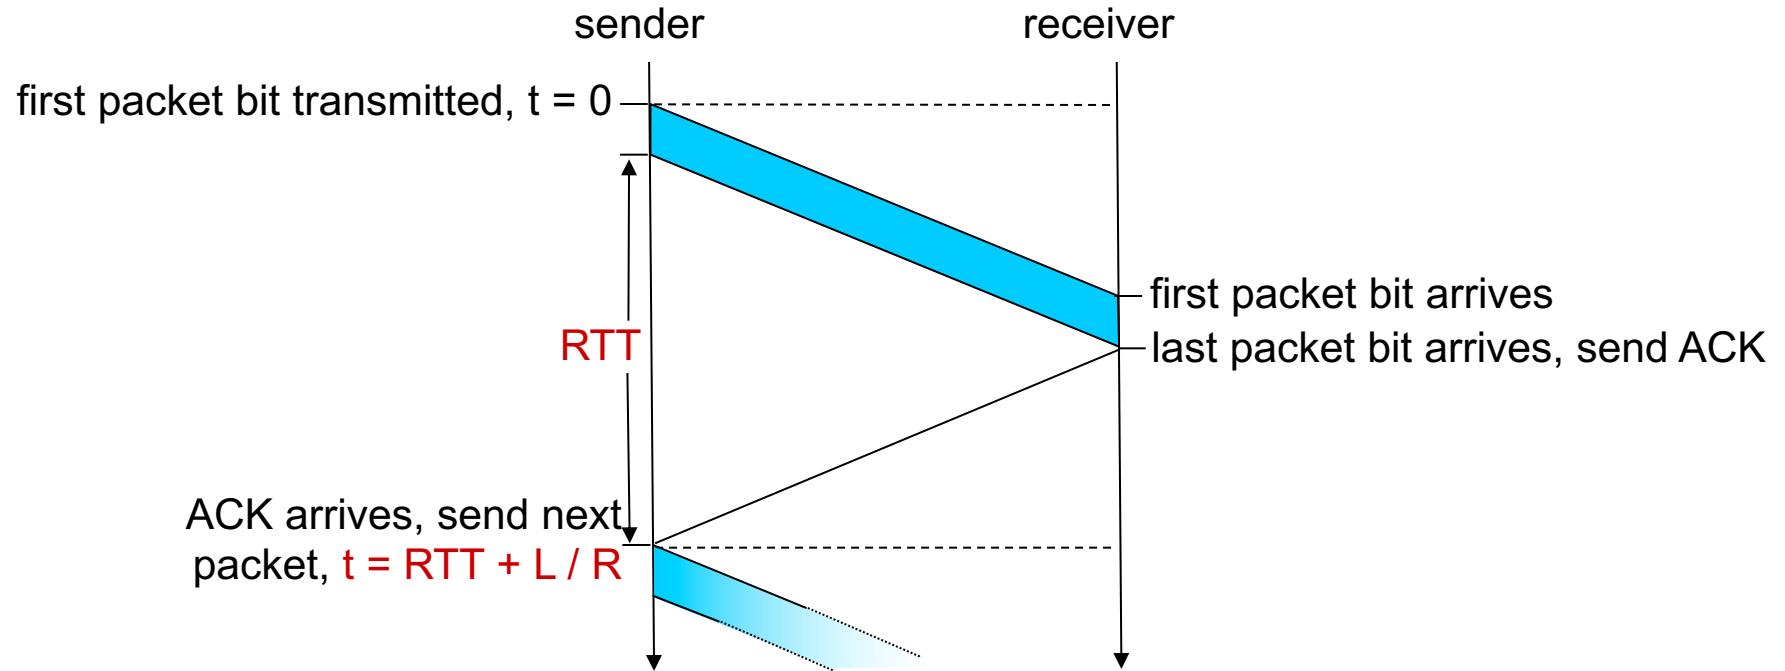

# rdt3.0: Efficiency

- $U_{sender}$ : *utilization* – fraction of time sender busy sending
- example: 1 Gbps link, 15 ms prop. delay, 8000 bit packet
  - time to transmit packet into channel:

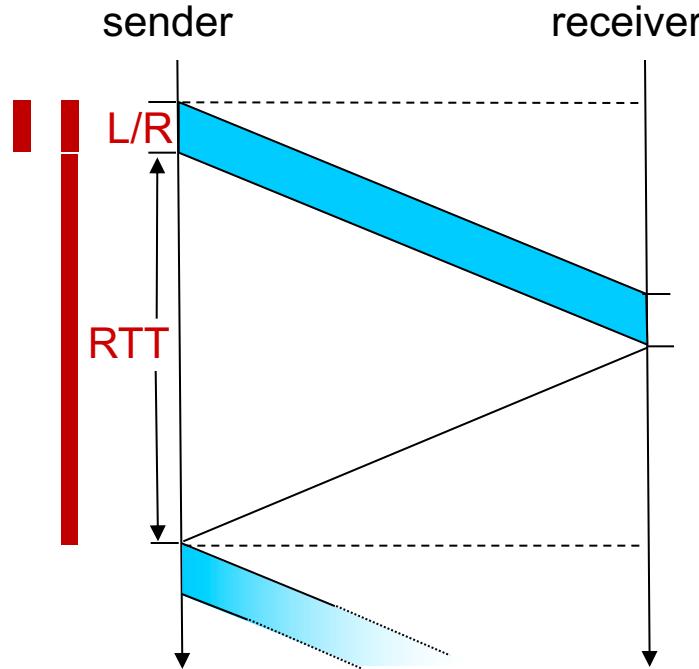

$$D_{trans} = \frac{L}{R} = \frac{8000 \text{ bits}}{10^9 \text{ bits/sec}} = 8 \text{ microsecs}$$

# rdt3.0: stop-and-wait operation

# rdt3.0: stop-and-wait operation

$$\begin{aligned} U_{\text{sender}} &= \frac{L / R}{RTT + L / R} \\ &= \frac{.008}{30.008} \\ &= 0.00027 \end{aligned}$$

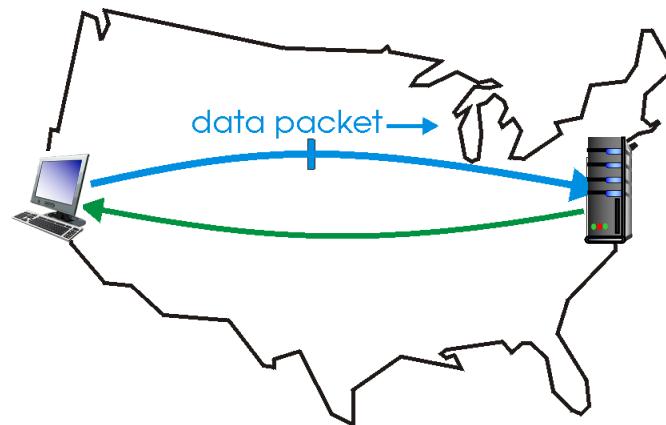

- rdt 3.0 protocol performance stinks!
- Protocol limits performance of underlying infrastructure (channel)

# rdt3.0: pipelined protocols operation

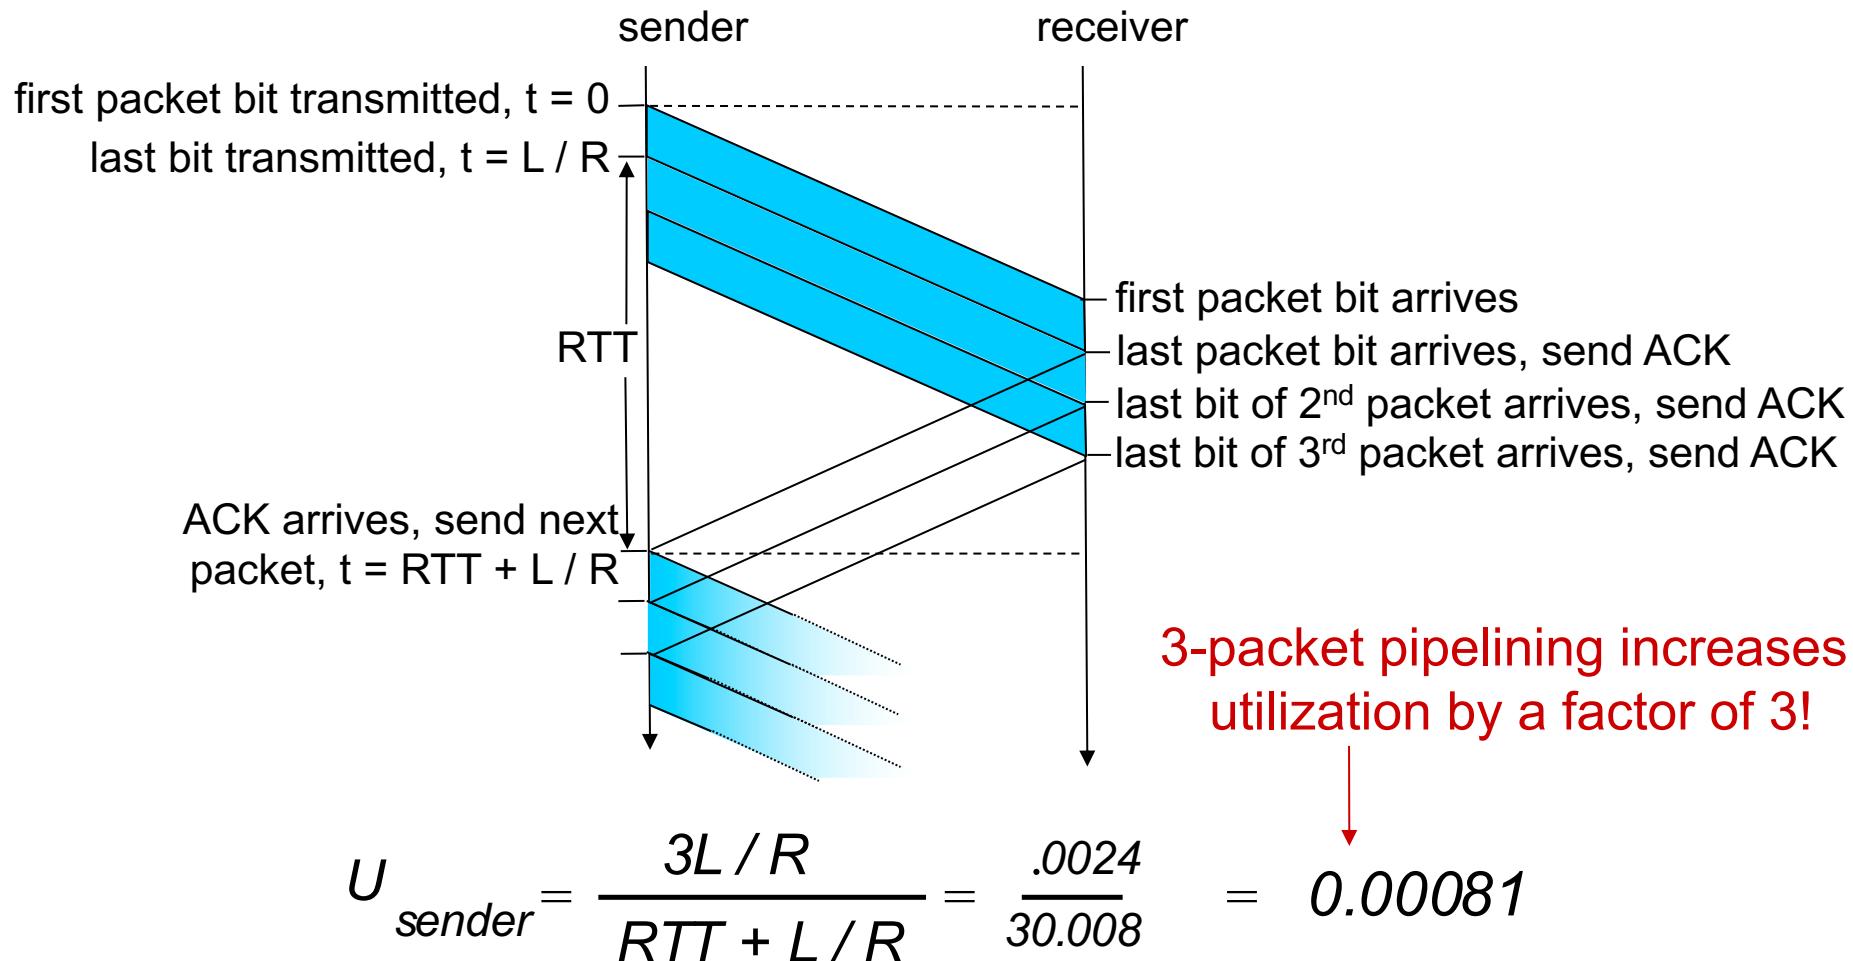

**pipelining:** sender allows multiple, “in-flight”, yet-to-be-acknowledged packets

- range of sequence numbers must be increased
- buffering at sender and/or receiver

(a) a stop-and-wait protocol in operation

# Pipelining: increased utilization

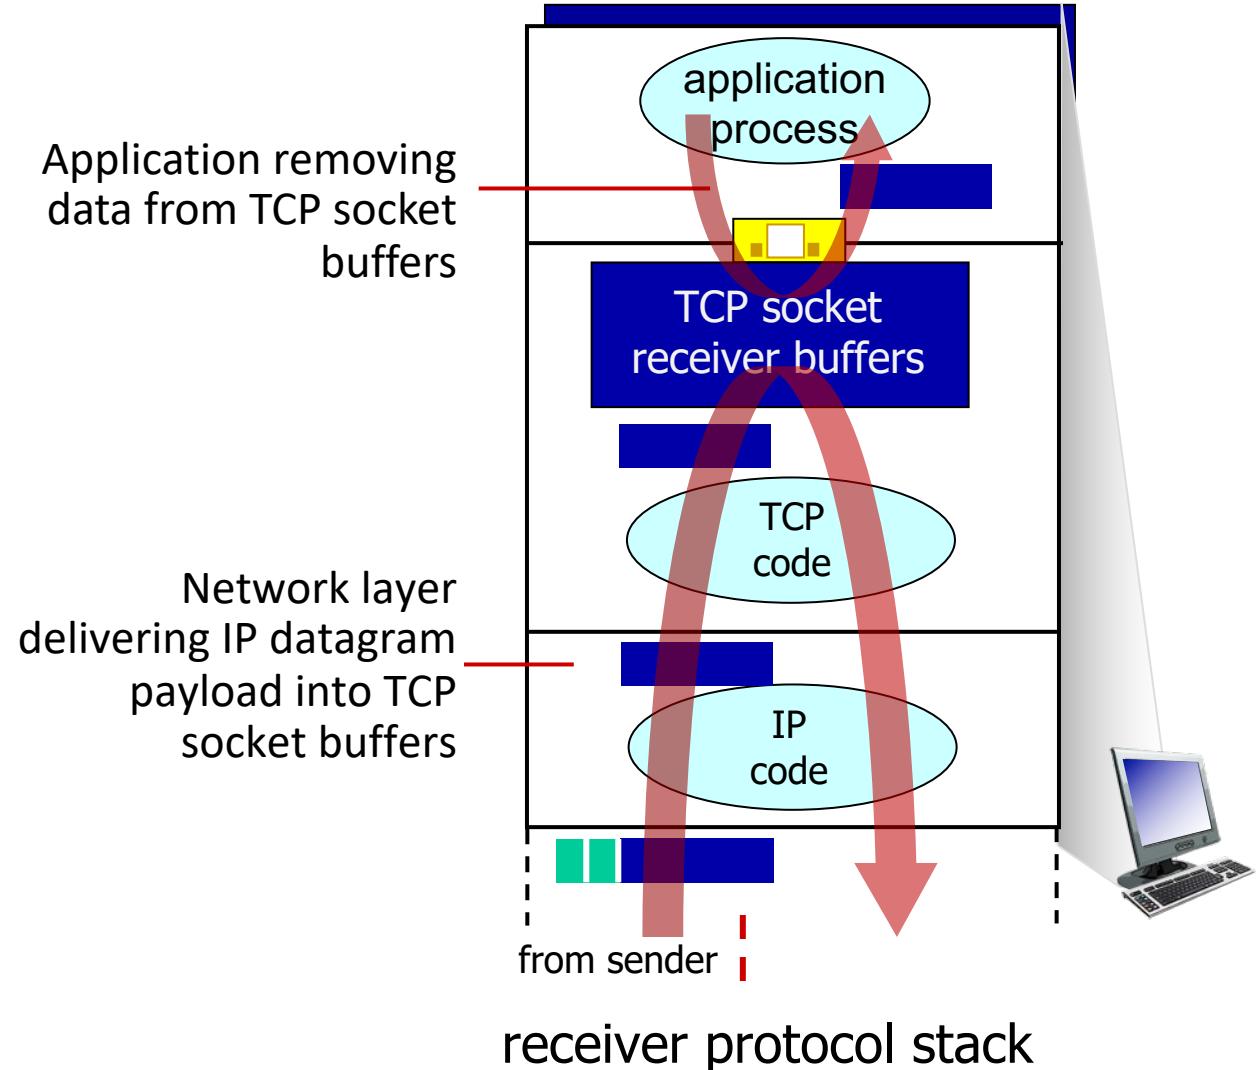

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- **Connection-oriented transport: TCP**
  - segment structure
  - reliable data transfer
  - flow control
  - connection management
- Principles of congestion control
- TCP congestion control

# TCP flow control

Q: What happens if network layer delivers data faster than application layer removes data from socket buffers?

# TCP flow control

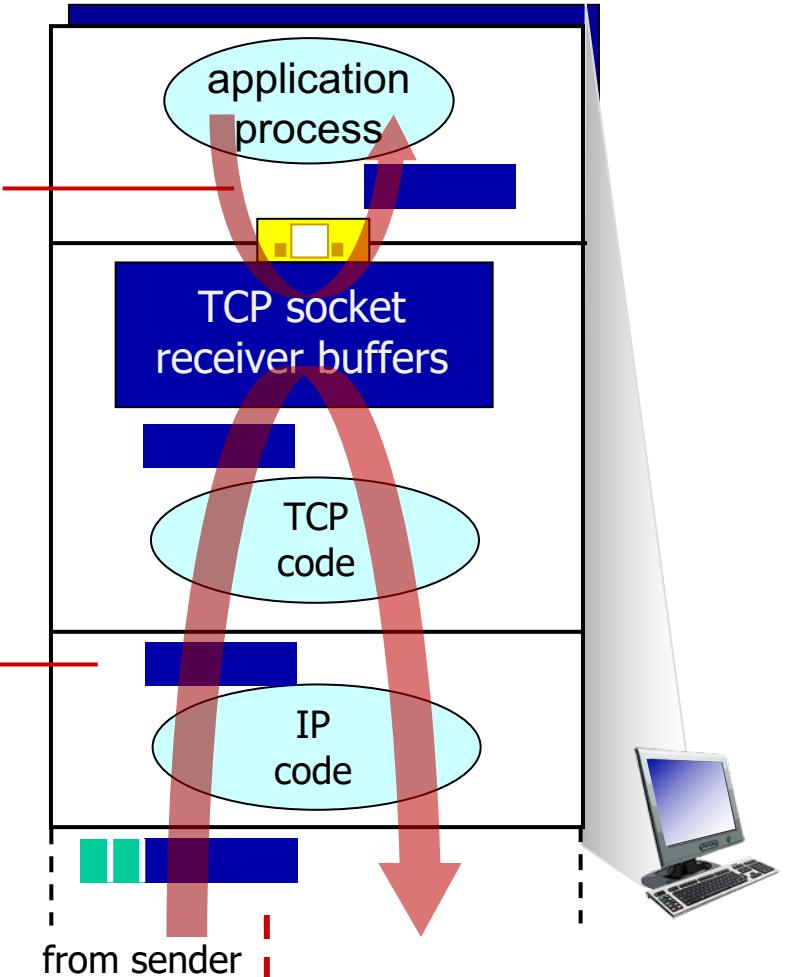

Q: What happens if network layer delivers data faster than application layer removes data from socket buffers?

Application removing data from TCP socket buffers

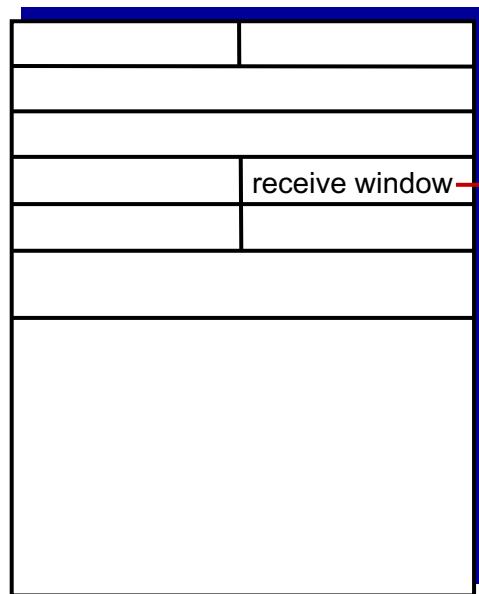

Network layer delivering IP datagram payload into TCP socket buffers

receiver protocol stack

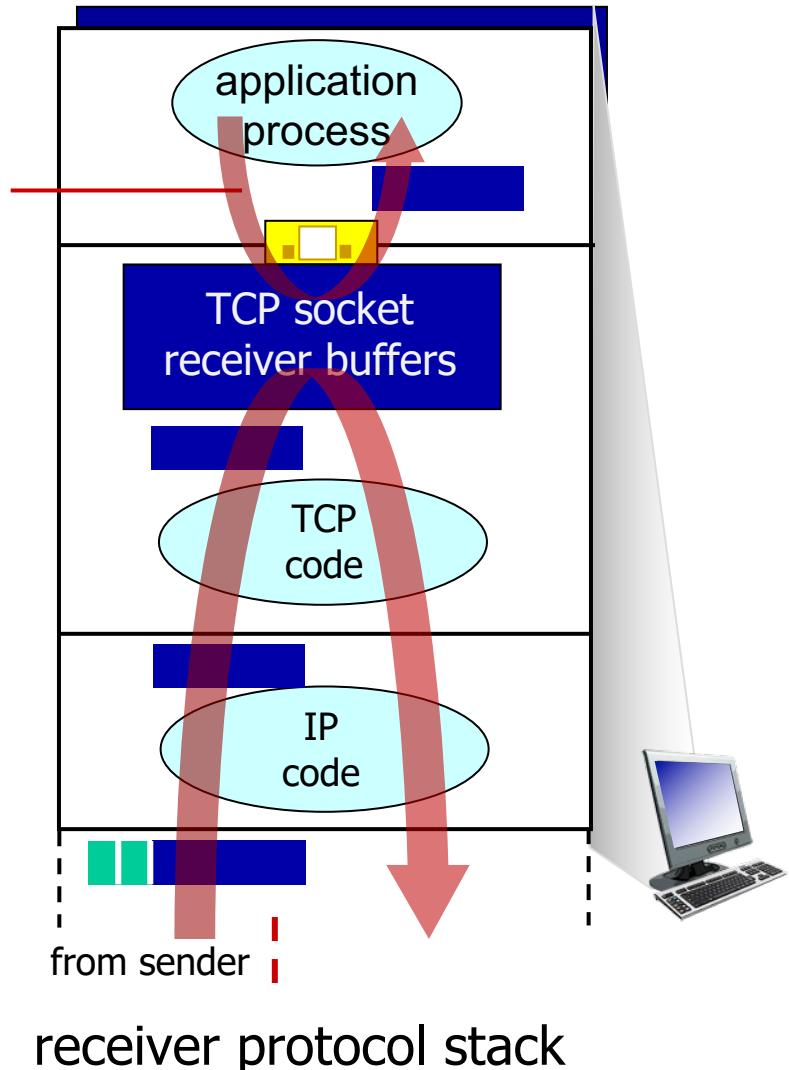

# TCP flow control

Q: What happens if network layer delivers data faster than application layer removes data from socket buffers?

flow control: # bytes receiver willing to accept

Application removing data from TCP socket buffers

receiver protocol stack

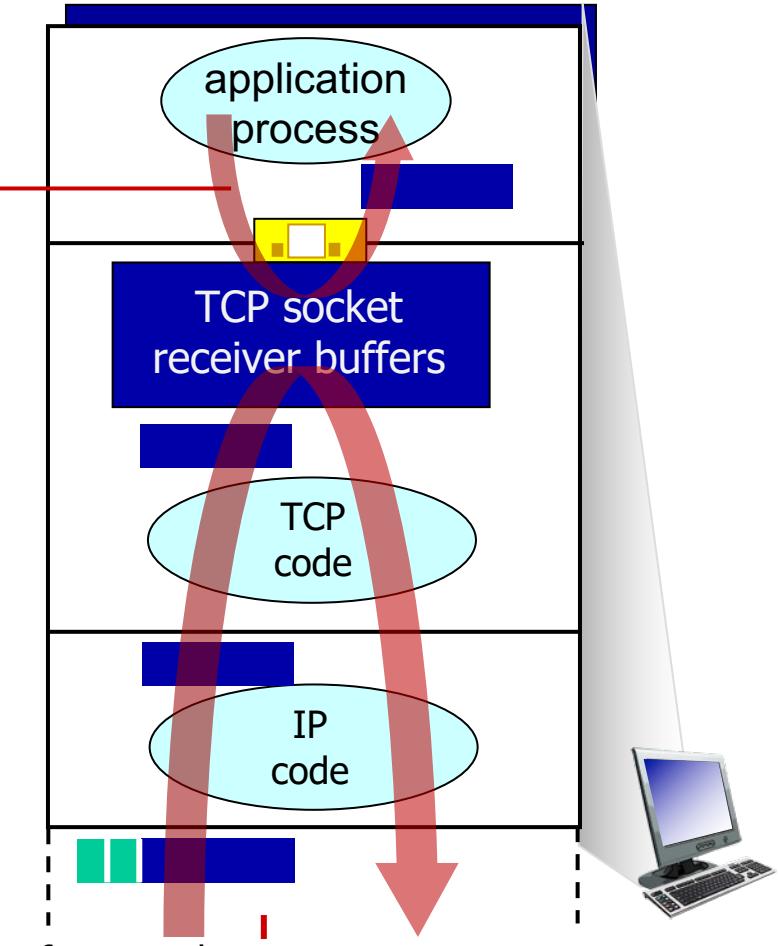

# TCP flow control

Q: What happens if network layer delivers data faster than application layer removes data from socket buffers?

## flow control

receiver controls sender, so sender won't overflow receiver's buffer by transmitting too much, too fast

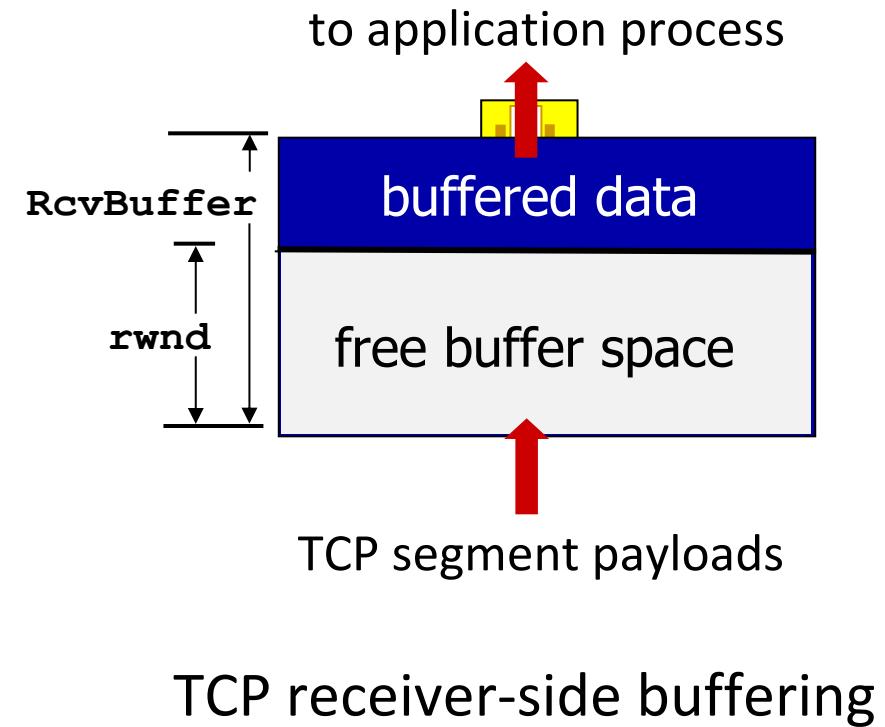

Application removing data from TCP socket buffers

receiver protocol stack

# TCP flow control

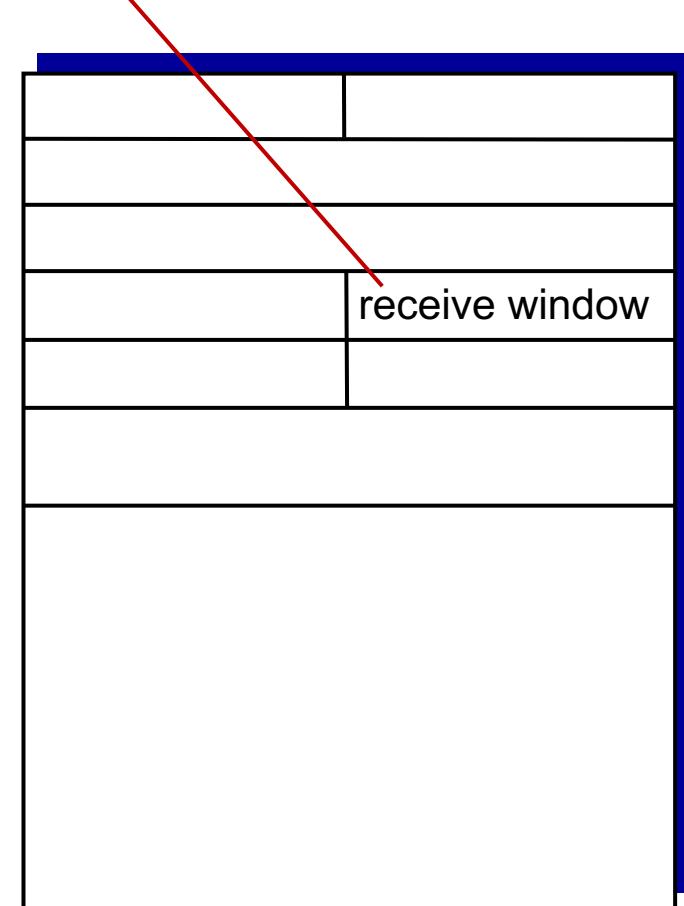

- TCP receiver “advertises” free buffer space in **rwnd** field in TCP header
  - **RcvBuffer** size set via socket options (typical default is 4096 bytes)
  - many operating systems auto-adjust **RcvBuffer**
- sender limits amount of unACKed (“in-flight”) data to received **rwnd**
- guarantees receive buffer will not overflow

# TCP flow control

- TCP receiver “advertises” free buffer space in **rwnd** field in TCP header
  - **RcvBuffer** size set via socket options (typical default is 4096 bytes)
  - many operating systems auto-adjust **RcvBuffer**
- sender limits amount of unACKed (“in-flight”) data to received **rwnd**
- guarantees receive buffer will not overflow

flow control: # bytes receiver willing to accept

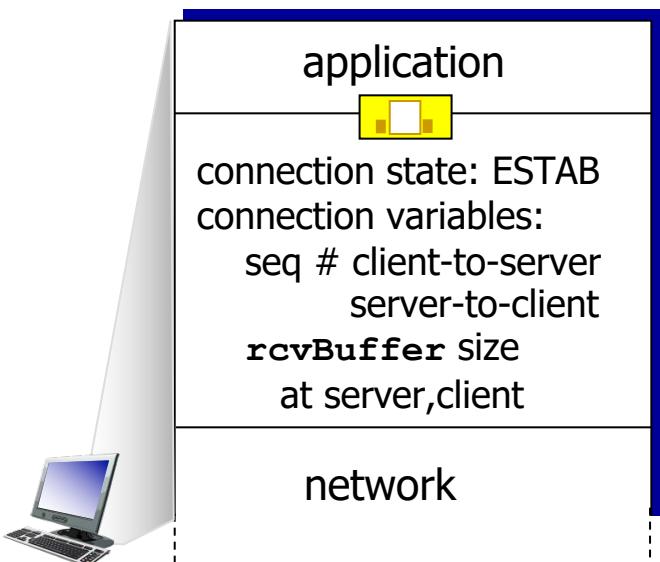

TCP segment format

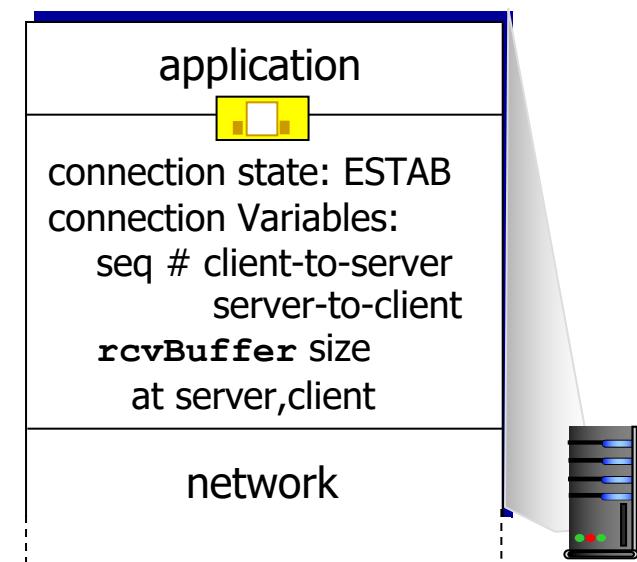

# TCP connection management

before exchanging data, sender/receiver “handshake”:

- agree to establish connection (each knowing the other willing to establish connection)
- agree on connection parameters (e.g., starting seq #s)

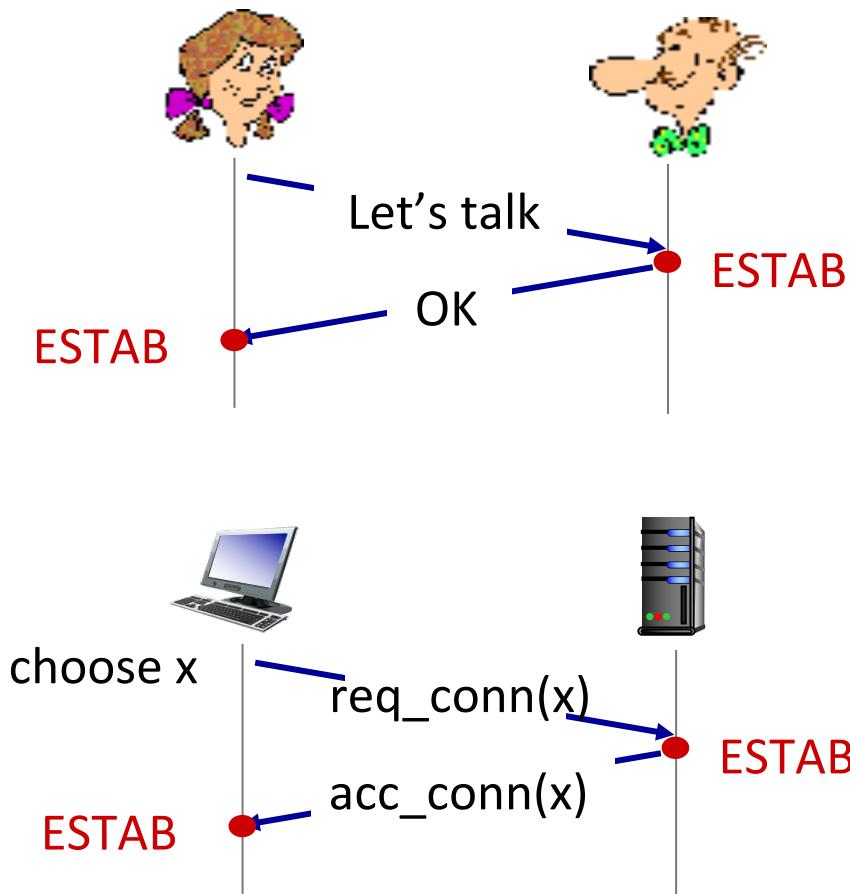

```
Socket clientSocket =  
    newSocket("hostname", "port number");
```

```
Socket connectionSocket =  
    welcomeSocket.accept();
```

# Agreeing to establish a connection

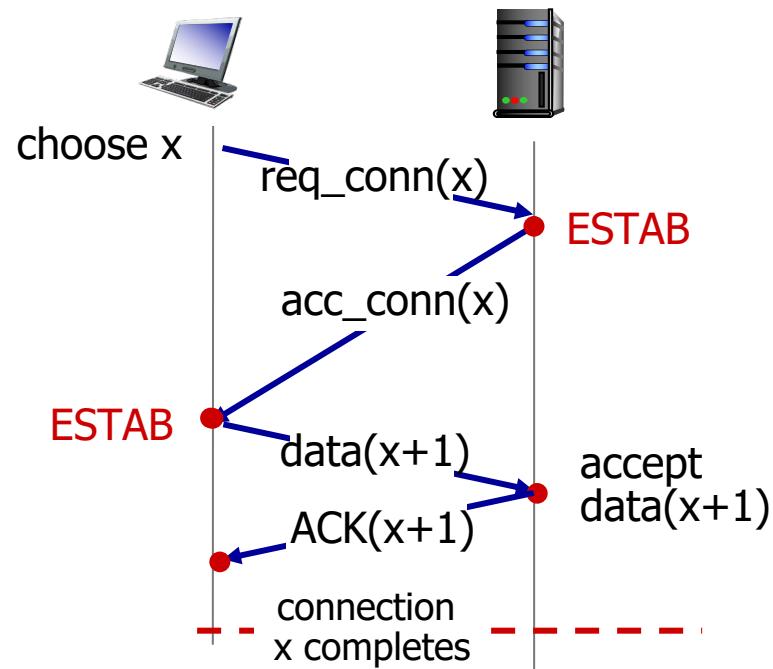

2-way handshake:

Q: will 2-way handshake always work in network?

- variable delays
- retransmitted messages (e.g.  $\text{req\_conn}(x)$ ) due to message loss
- message reordering
- can't “see” other side

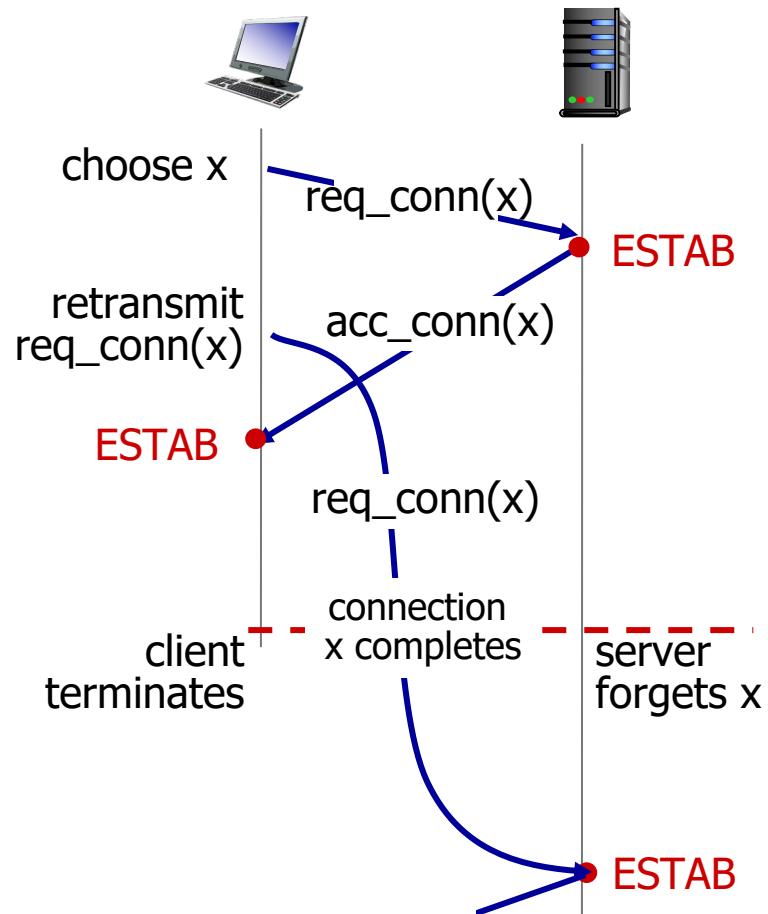

# 2-way handshake scenarios

No problem!

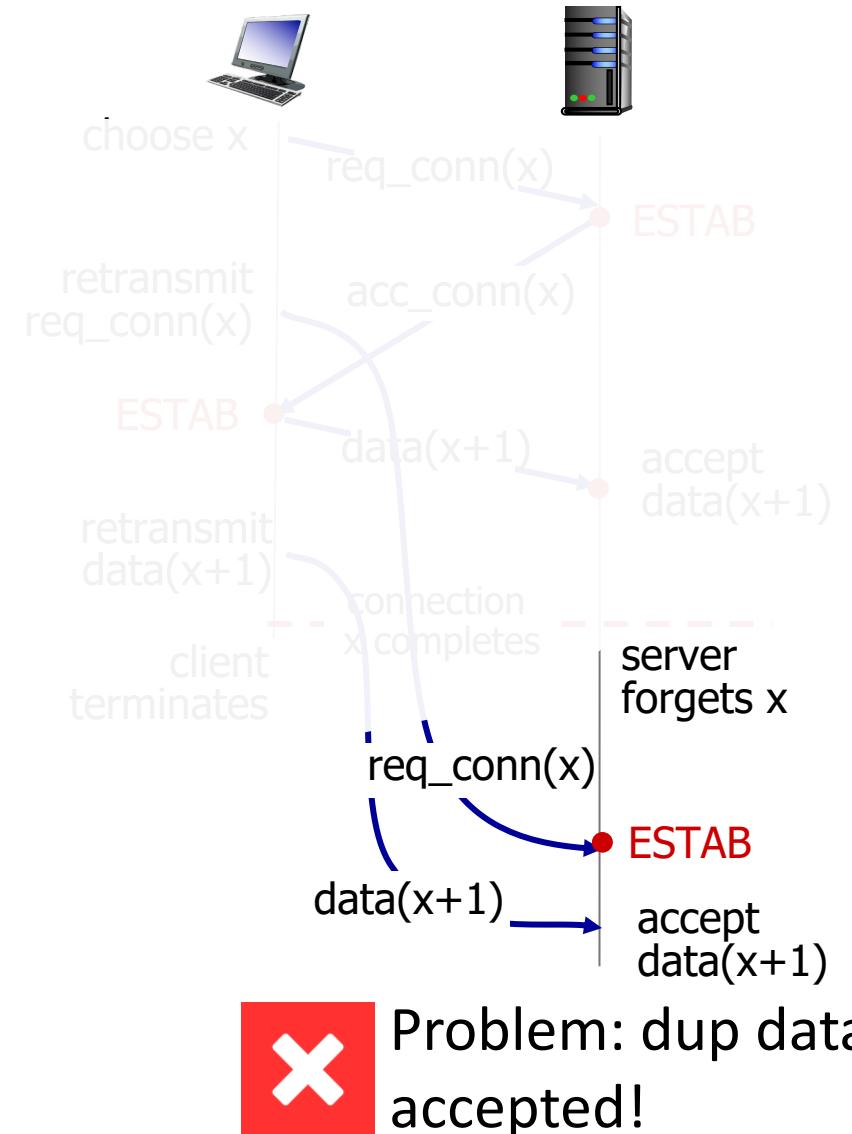

# 2-way handshake scenarios

Problem: half open  
connection! (no client)

# 2-way handshake scenarios

# TCP 3-way handshake

## Client state

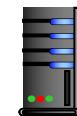

```
clientSocket = socket(AF_INET, SOCK_STREAM)
```

LISTEN

```
clientSocket.connect((serverName, serverPort))
```

SYNSENT

choose init seq num, x  
send TCP SYN msg

SYNbit=1, Seq=x

ESTAB

received SYNACK(x)  
indicates server is live;  
send ACK for SYNACK;  
this segment may contain  
client-to-server data

SYNbit=1, Seq=y  
ACKbit=1; ACKnum=x+1

ACKbit=1, ACKnum=y+1

## Server state

```
serverSocket = socket(AF_INET, SOCK_STREAM)  
serverSocket.bind(('', serverPort))  
serverSocket.listen(1)  
connectionSocket, addr = serverSocket.accept()
```

LISTEN

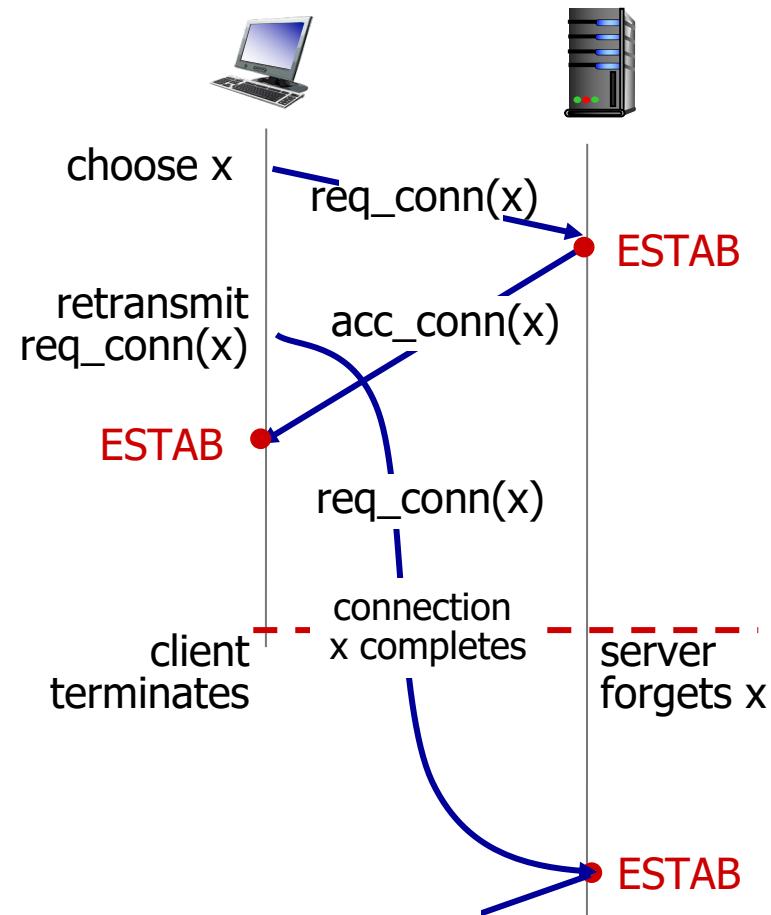

SYN RCVD

choose init seq num, y  
send TCP SYNACK  
msg, acking SYN

ESTAB

received ACK(y)  
indicates client is live

# 2-way handshake scenarios

Problem: half open  
connection! (no client)

# A human 3-way handshake protocol

# Closing a TCP connection

- client, server each close their side of connection
  - send TCP segment with FIN bit = 1
- respond to received FIN with ACK
  - on receiving FIN, ACK can be combined with own FIN
- simultaneous FIN exchanges can be handled

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- **Principles of congestion control**
- TCP congestion control
- Evolution of transport-layer functionality

# Principles of congestion control

## Congestion:

- informally: “too many sources sending too much data too fast for *network* to handle”
- manifestations:
  - long delays (queueing in router buffers)
  - packet loss (buffer overflow at routers)
- different from flow control!
- a top-10 problem!

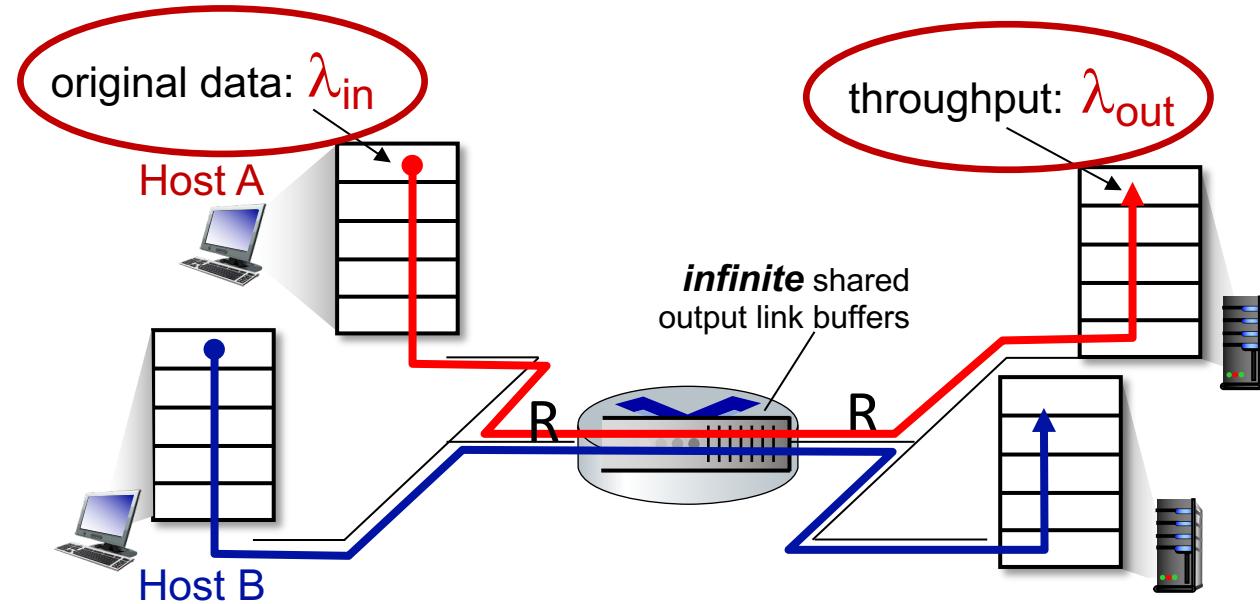

**congestion control:**  
too many senders,  
sending too fast

**flow control:** one sender  
too fast for one receiver

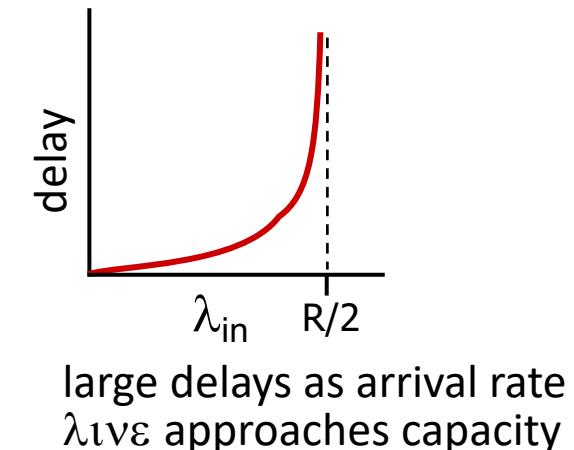

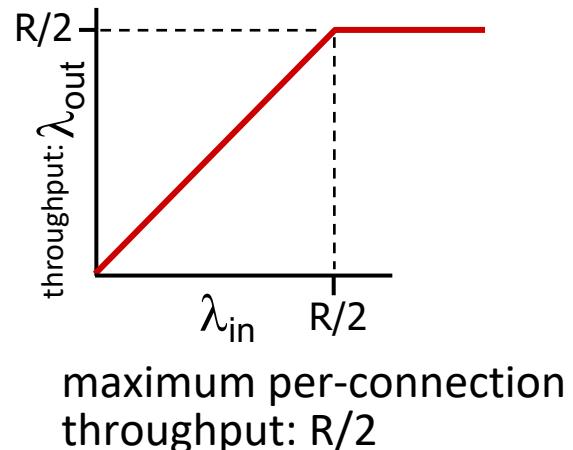

# Causes/costs of congestion: scenario 1

Simplest scenario:

- one router, infinite buffers
- input, output link capacity:  $R$
- two flows
- no retransmissions needed

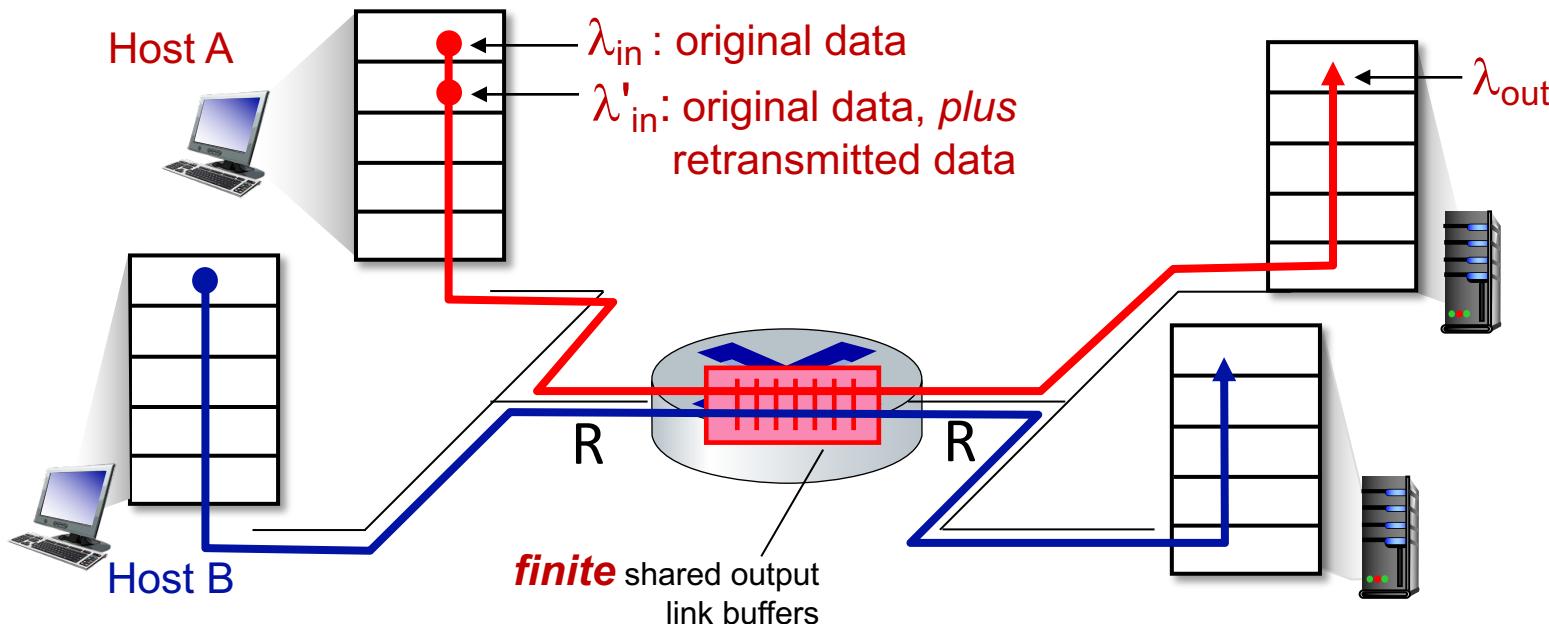

**Q:** What happens as arrival rate  $\lambda_{in}$  approaches  $R/2$ ?

# Causes/costs of congestion: scenario 2

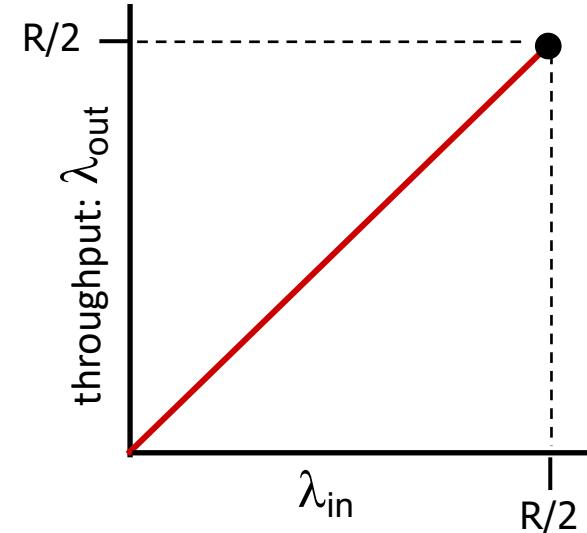

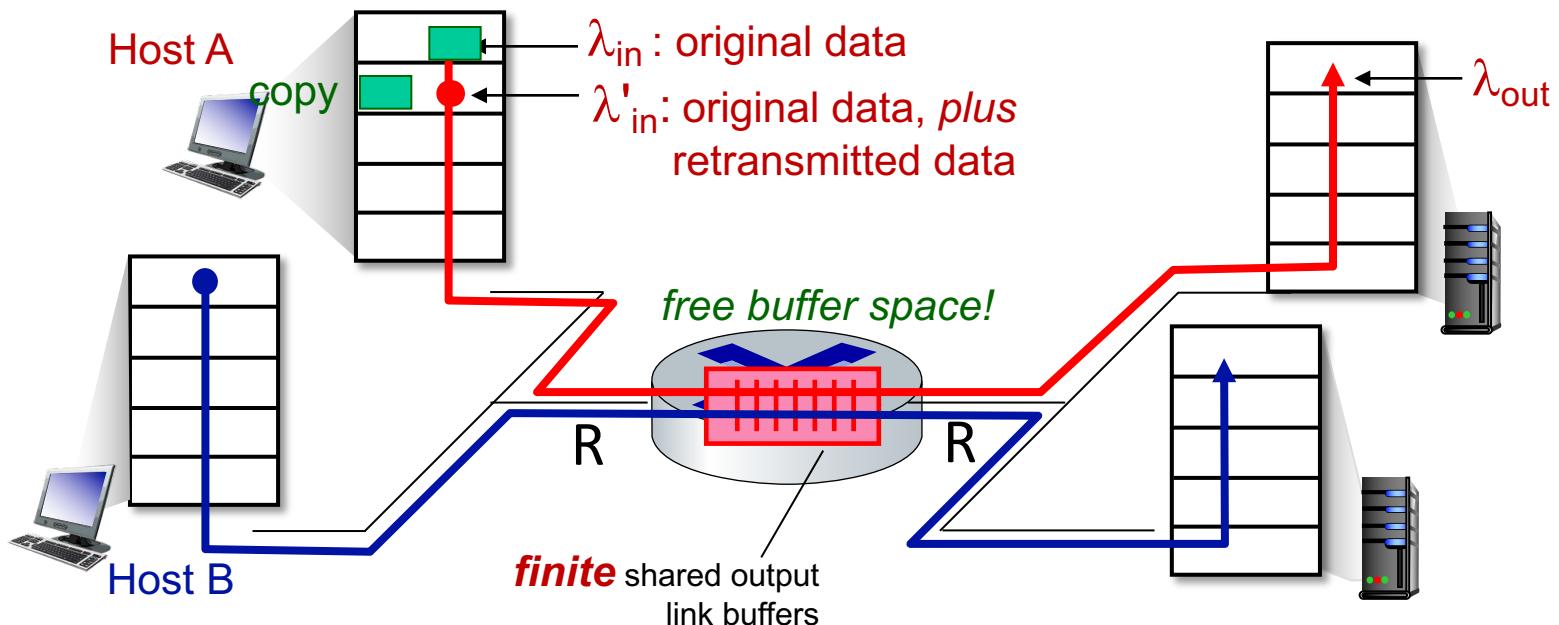

- one router, *finite* buffers
- sender retransmits lost, timed-out packet
  - application-layer input = application-layer output:  $\lambda_{in} = \lambda_{out}$
  - transport-layer input includes *retransmissions* :  $\lambda'_{in} \geq \lambda_{in}$

# Causes/costs of congestion: scenario 2

Idealization: perfect knowledge

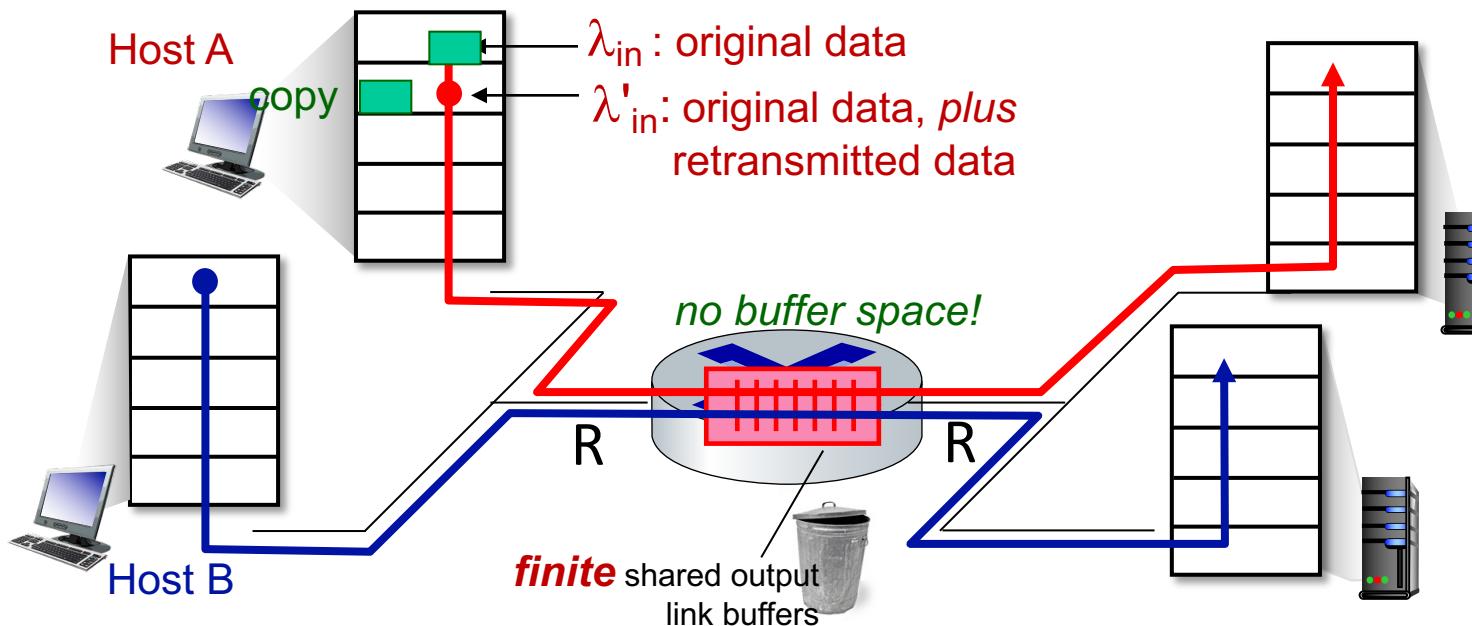

- sender sends only when router buffers available

# Causes/costs of congestion: scenario 2

Idealization: *some* perfect knowledge

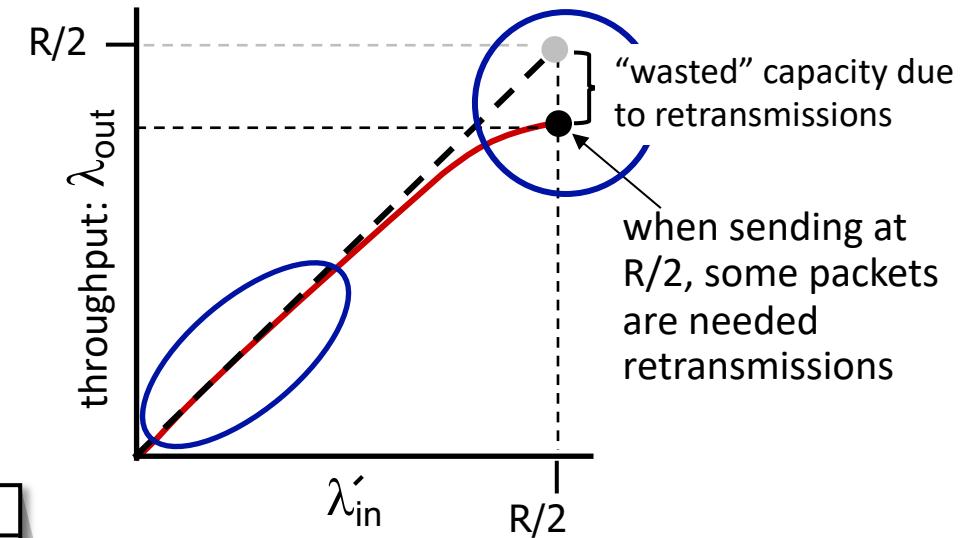

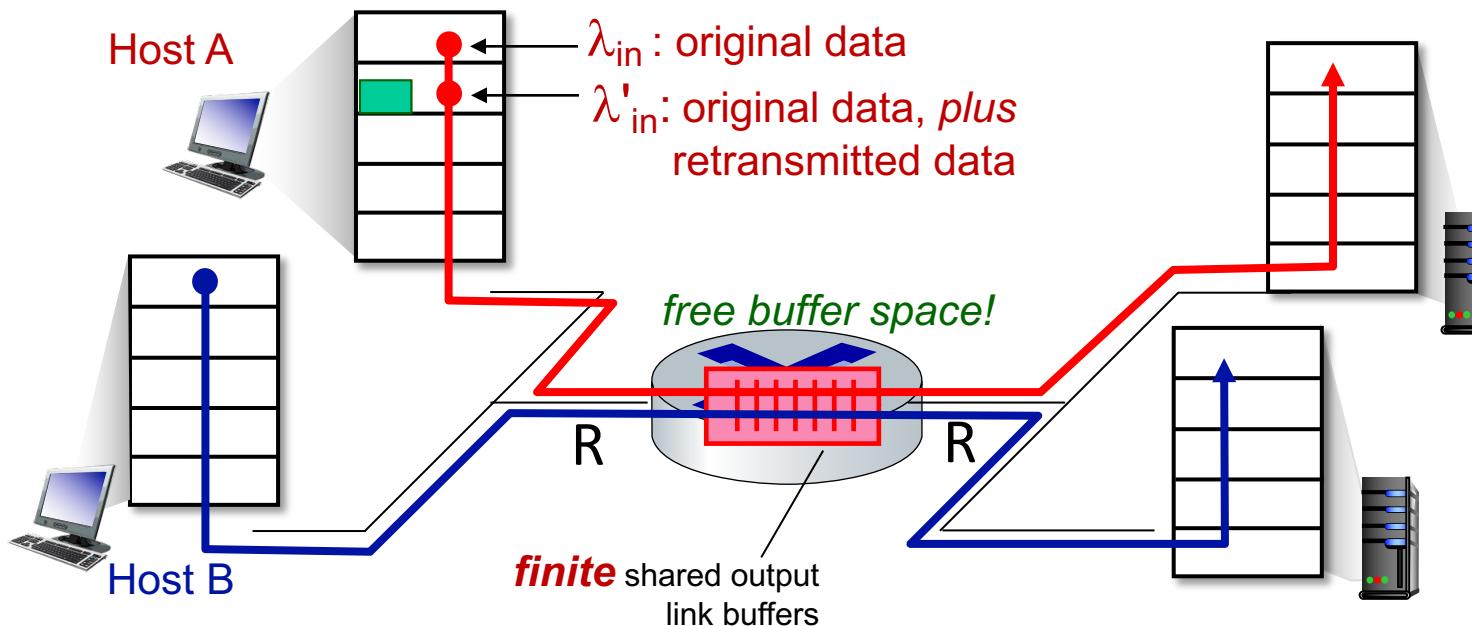

- packets can be lost (dropped at router) due to full buffers
- sender knows when packet has been dropped: only resends if packet *known* to be lost

# Causes/costs of congestion: scenario 2

Idealization: *some* perfect knowledge

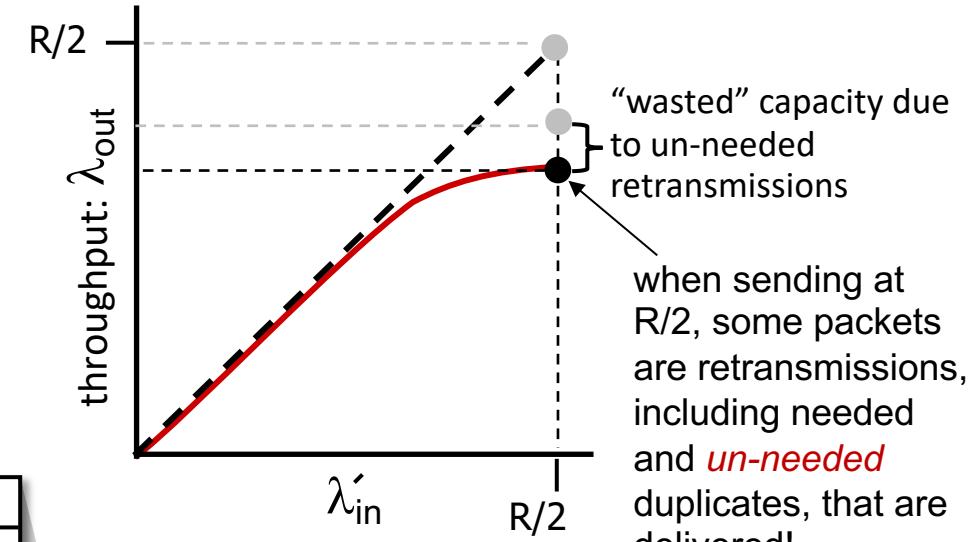

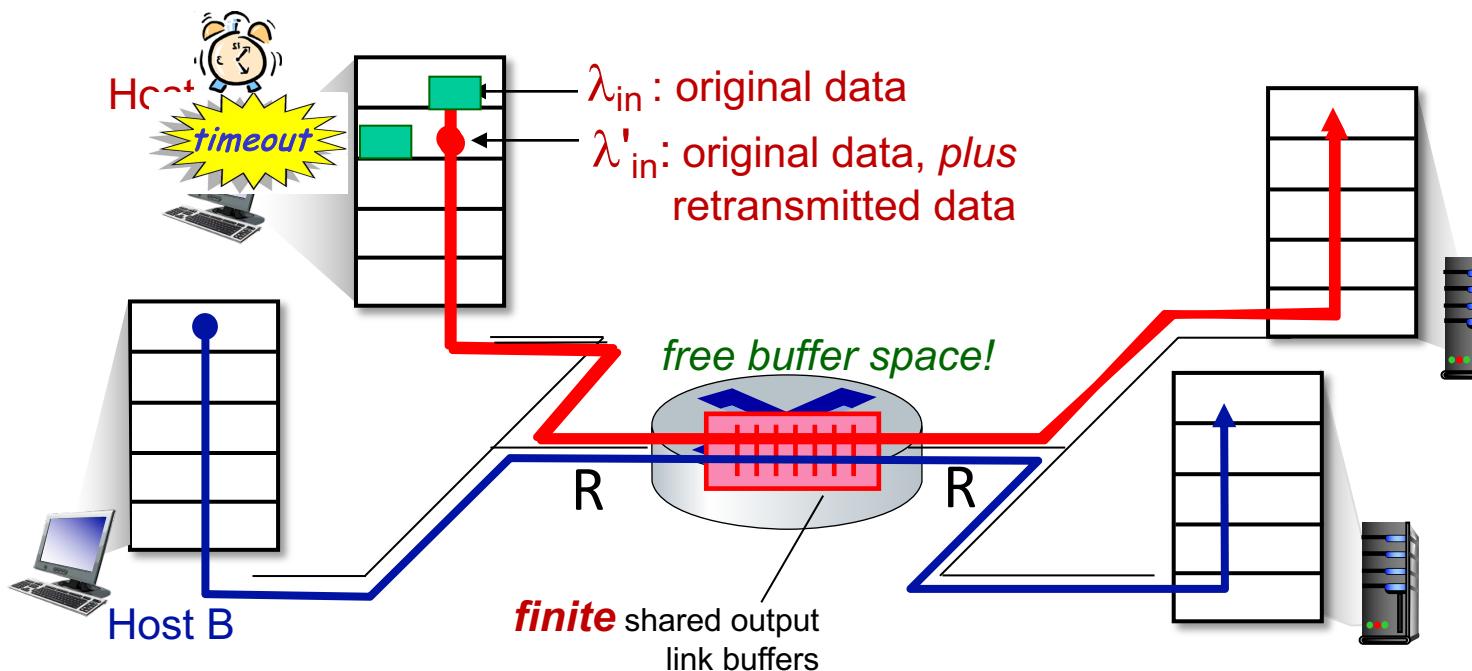

- packets can be lost (dropped at router) due to full buffers
- sender knows when packet has been dropped: only resends if packet *known* to be lost

# Causes/costs of congestion: scenario 2

## Realistic scenario: *un-needed duplicates*

- packets can be lost, dropped at router due to full buffers – requiring retransmissions
- but sender times can time out prematurely, sending *two* copies, *both* of which are delivered

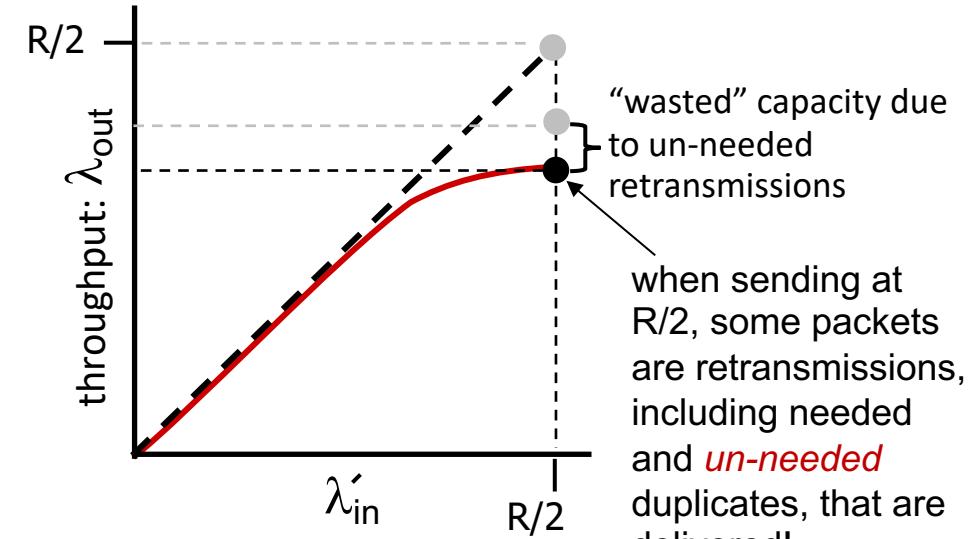

# Causes/costs of congestion: scenario 2

## Realistic scenario: *un-needed duplicates*

- packets can be lost, dropped at router due to full buffers – requiring retransmissions
- but sender times can time out prematurely, sending *two* copies, *both* of which are delivered

## “costs” of congestion:

- more work (retransmission) for given receiver throughput
- unneeded retransmissions: link carries multiple copies of a packet
  - decreasing maximum achievable throughput

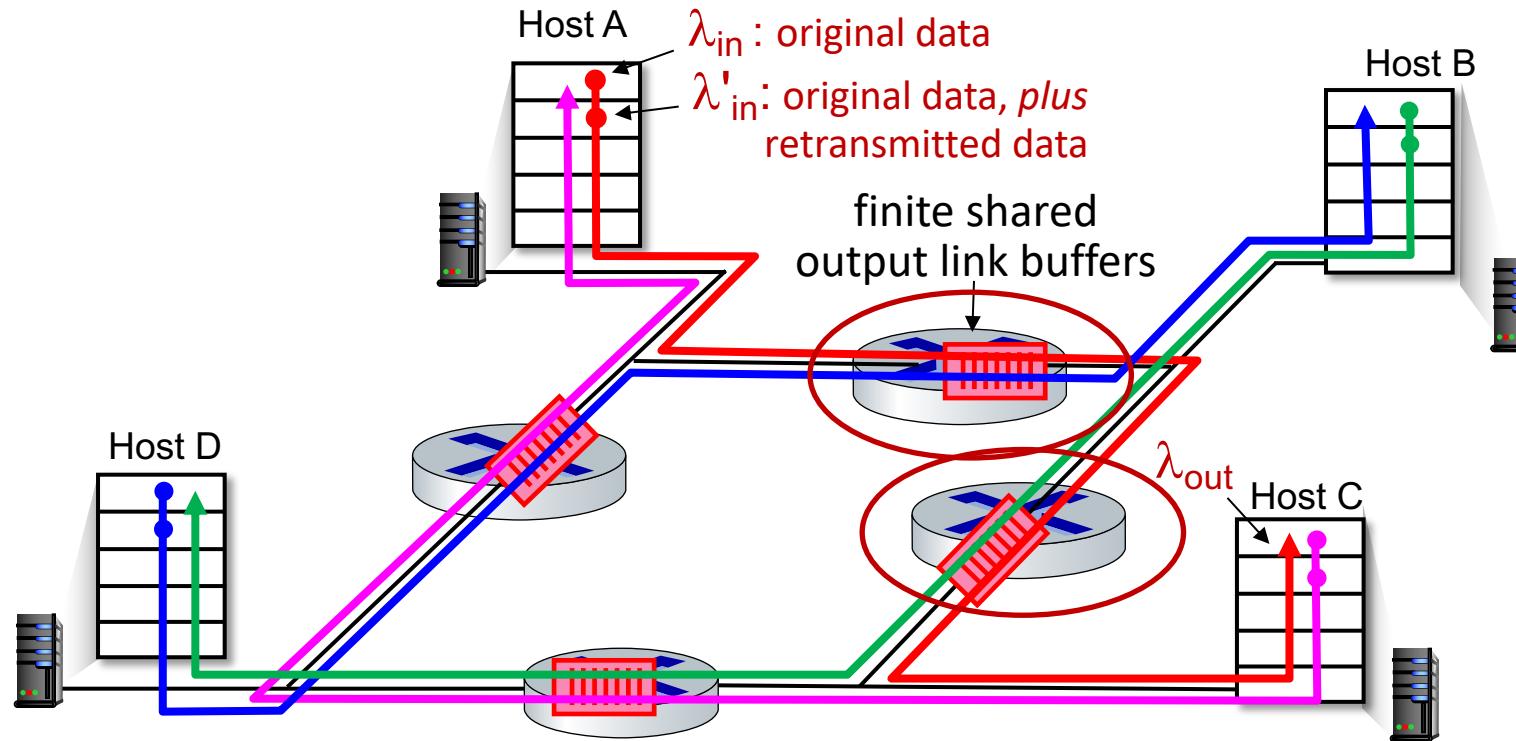

# Causes/costs of congestion: scenario 3

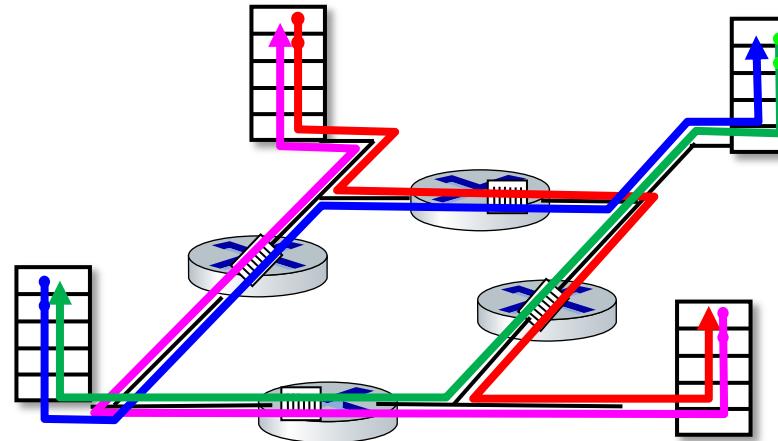

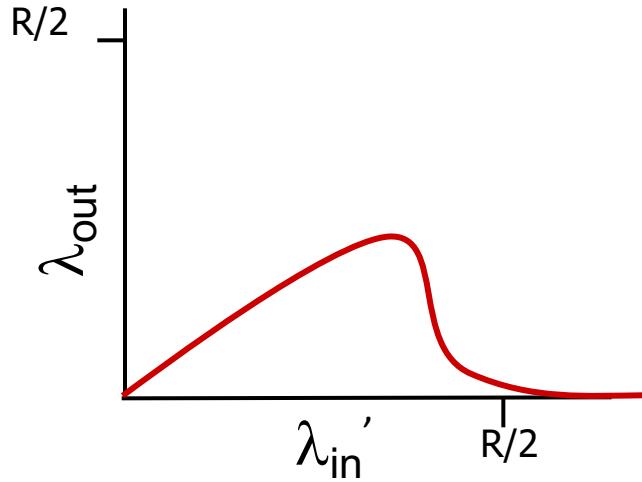

- four senders
- multi-hop paths
- timeout/retransmit

**Q:** what happens as  $\lambda_{in}$  and  $\lambda'_{in}$  increase ?

**A:** as red  $\lambda'_{in}$  increases, all arriving blue pkts at upper queue are dropped, blue throughput  $\rightarrow 0$

# Causes/costs of congestion: scenario 3

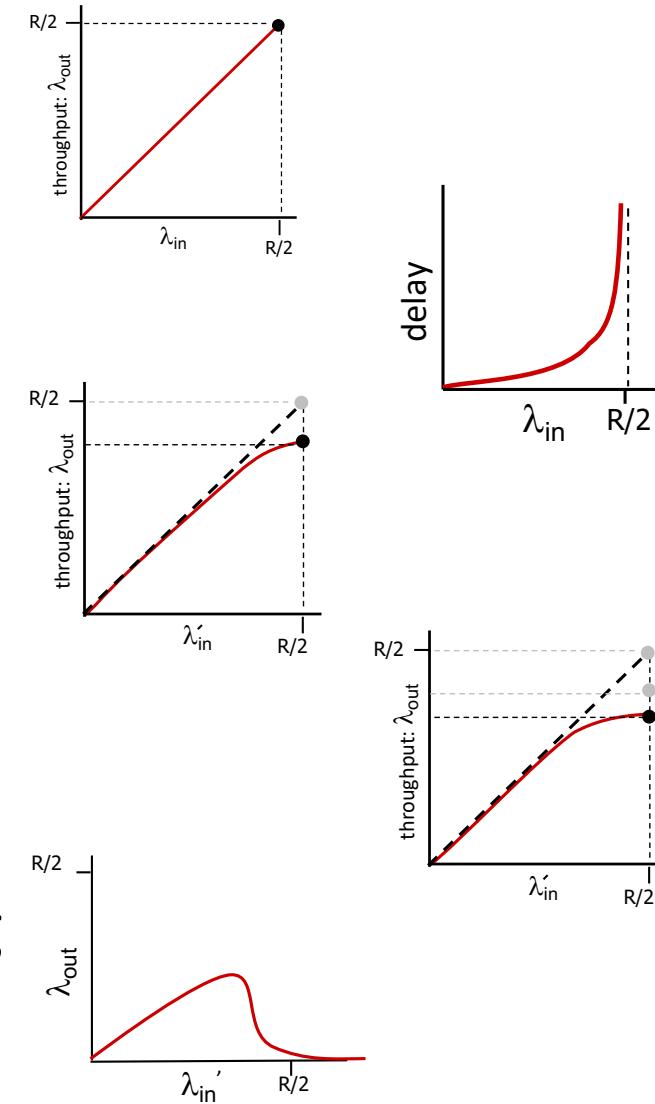

another “cost” of congestion:

- when packet dropped, any upstream transmission capacity and buffering used for that packet was wasted!

# Causes/costs of congestion: insights

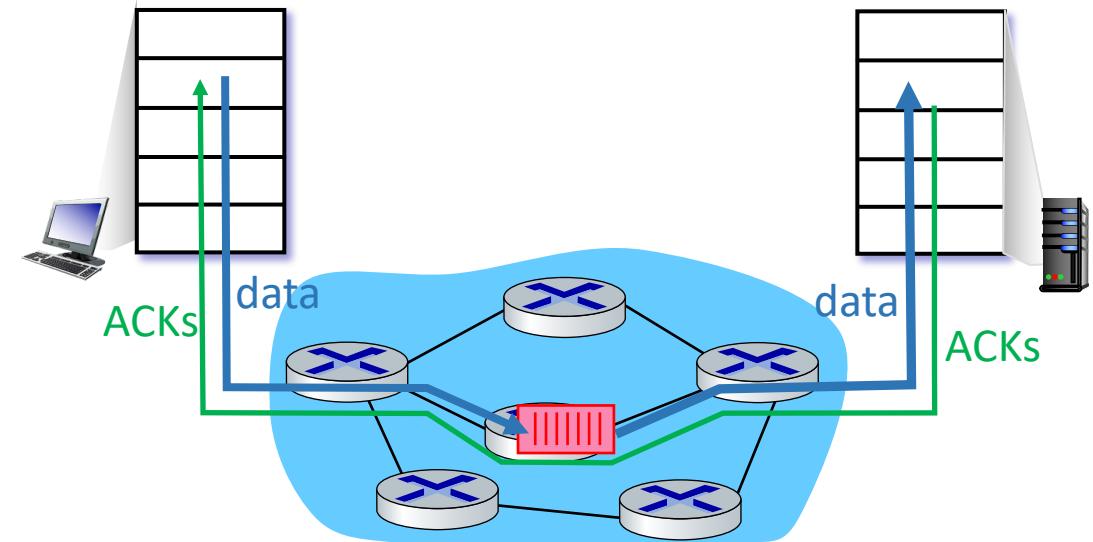

- throughput can never exceed capacity
- delay increases as capacity approached
- loss/retransmission decreases effective throughput
- un-needed duplicates further decreases effective throughput
- upstream transmission capacity / buffering wasted for packets lost downstream

# Approaches towards congestion control

## End-end congestion control:

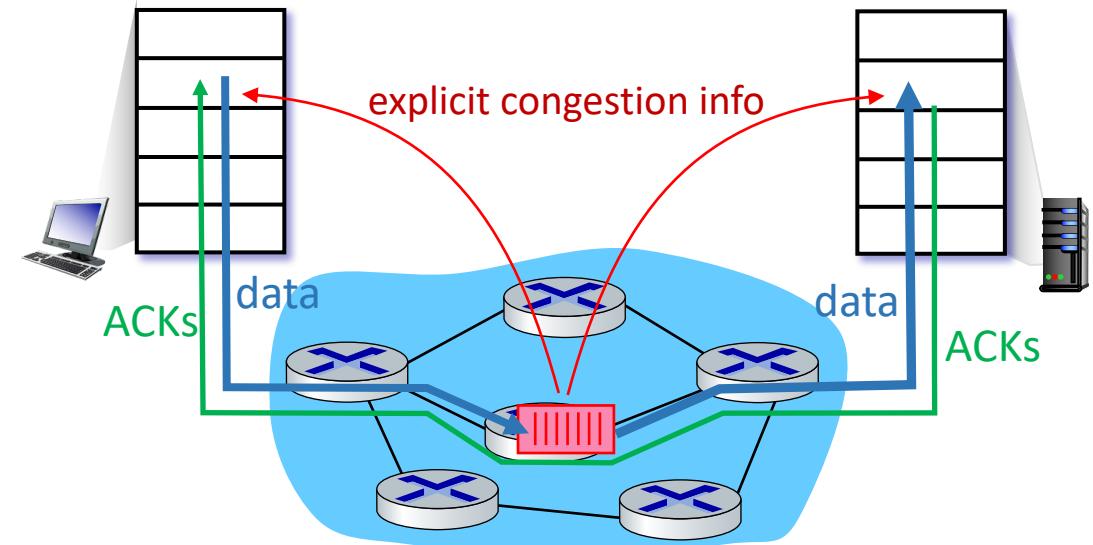

- no explicit feedback from network
- congestion *inferred* from observed loss, delay
- approach taken by TCP

# Approaches towards congestion control

## Network-assisted congestion control:

- routers provide *direct* feedback to sending/receiving hosts with flows passing through congested router
- may indicate congestion level or explicitly set sending rate
- TCP ECN, ATM, DECbit protocols

# Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- **TCP congestion control**
- Evolution of transport-layer functionality

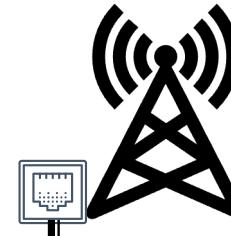

A cellular-based connection consists a wired Internet hop and a **wireless** last hop

**Cloud servers**

**Base station**

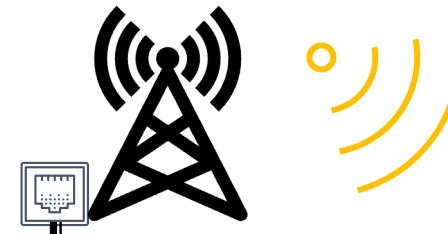

Wired Internet

A cellular-based connection consists a wired Internet hop and a wireless last hop

Cloud servers

Base station

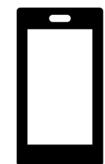

Wired Internet

Gbps

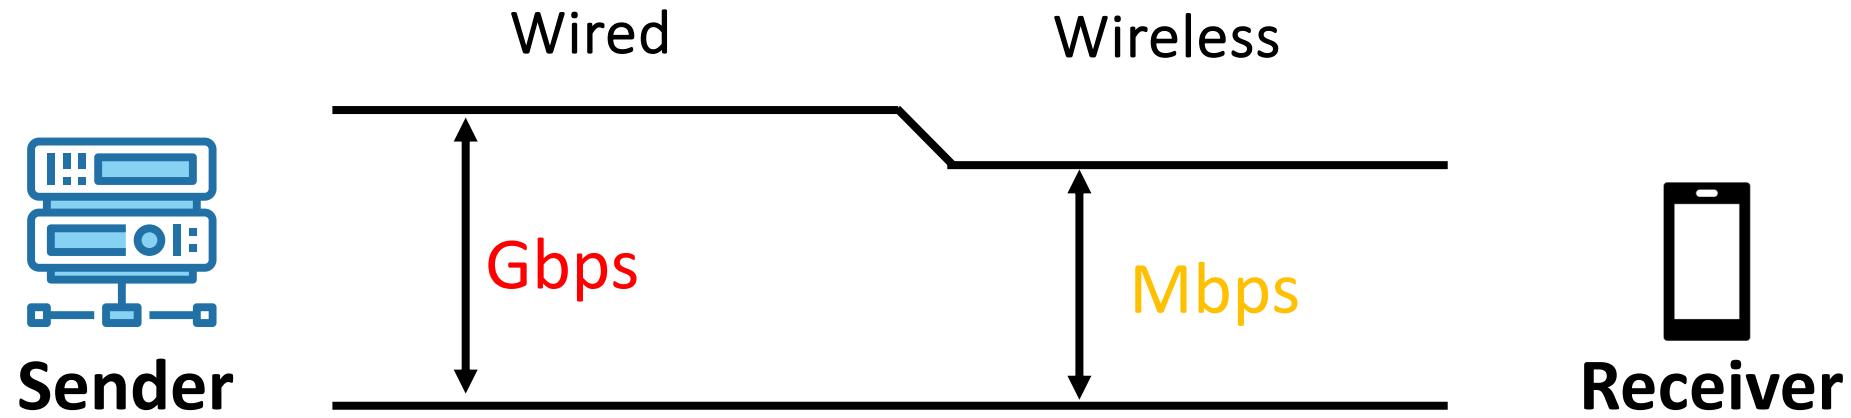

Wireless last hop

Mbps

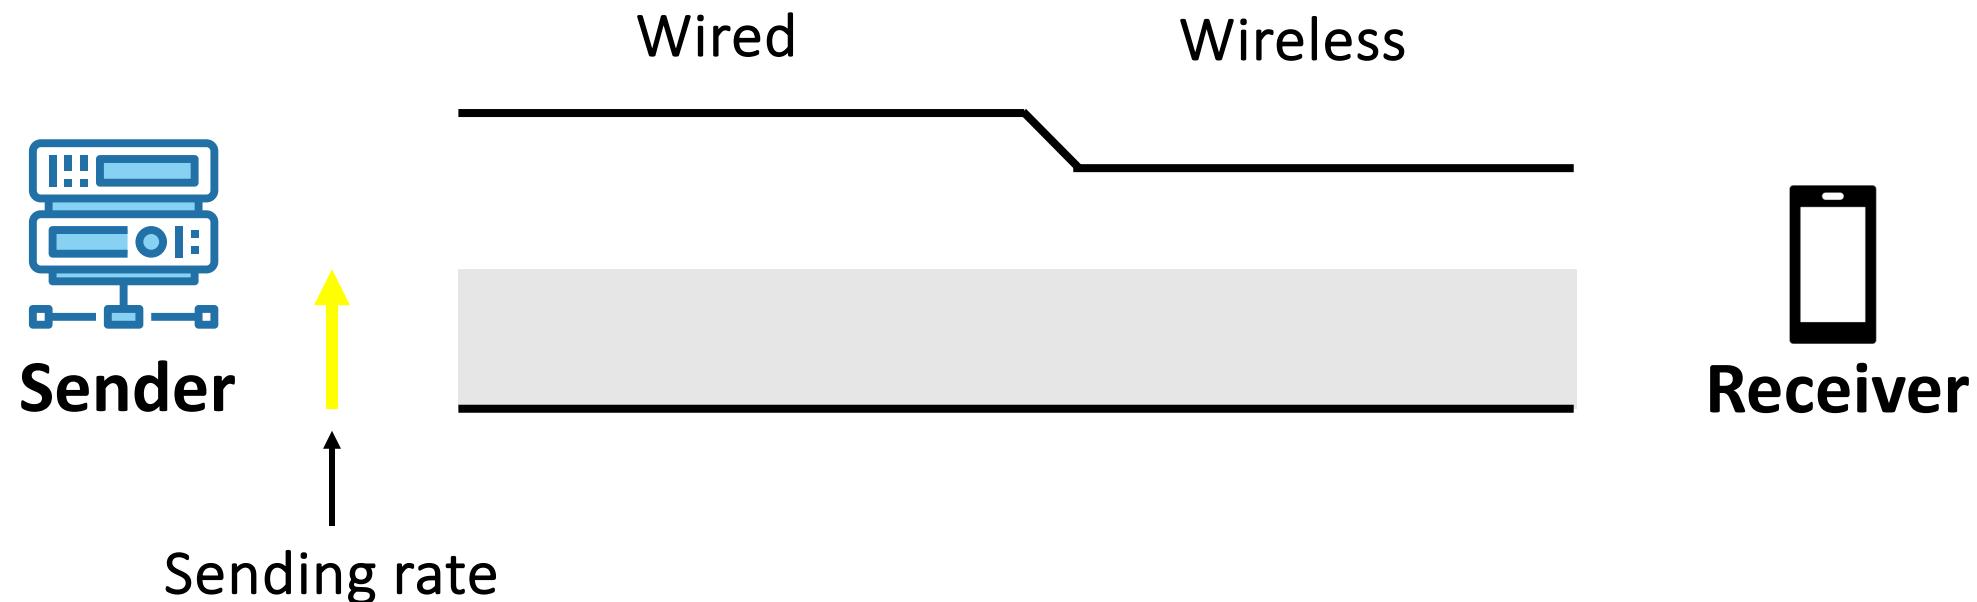

IoT devices

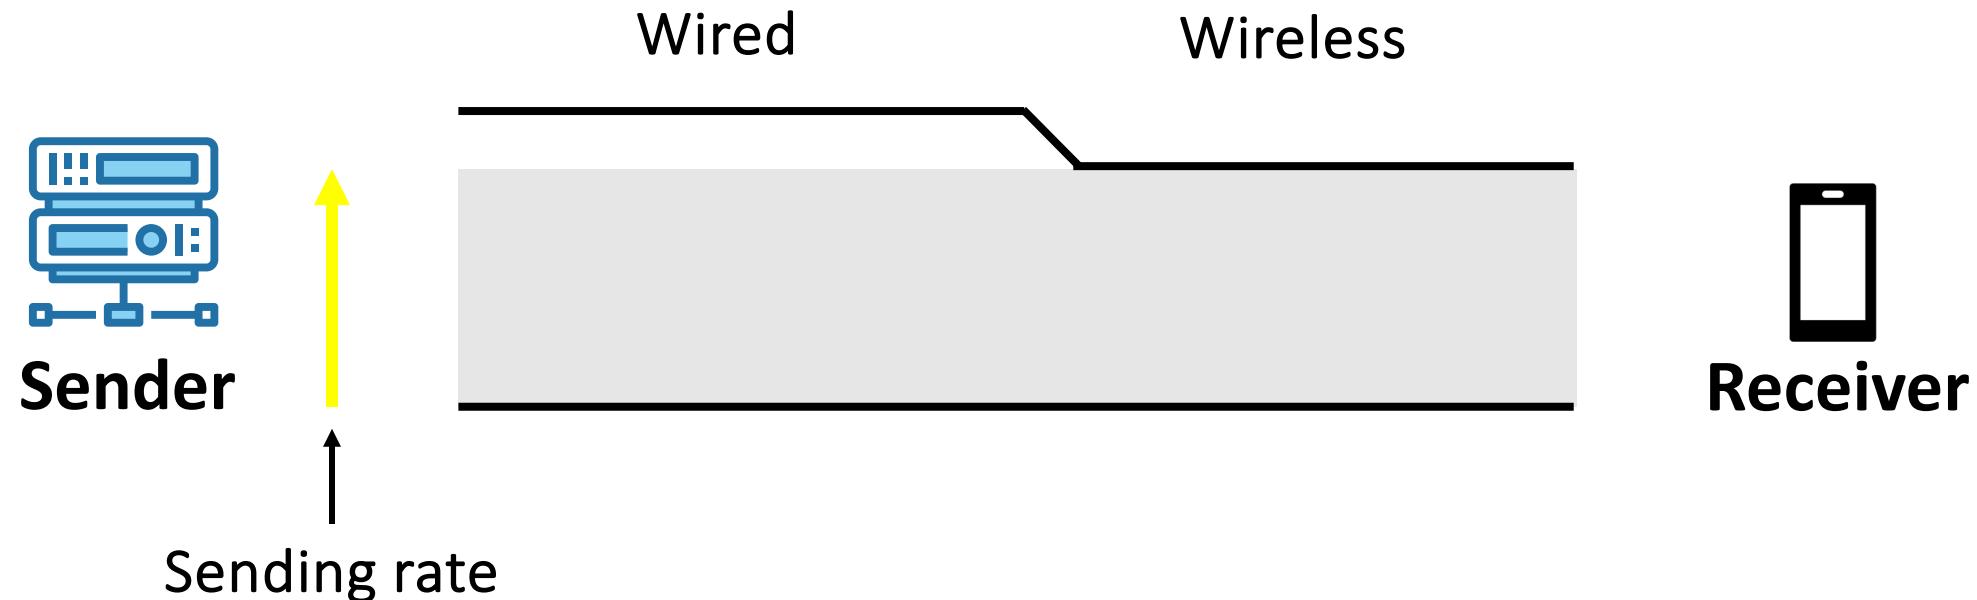

Capacity of wireless hop determines the upper bound of achievable throughput

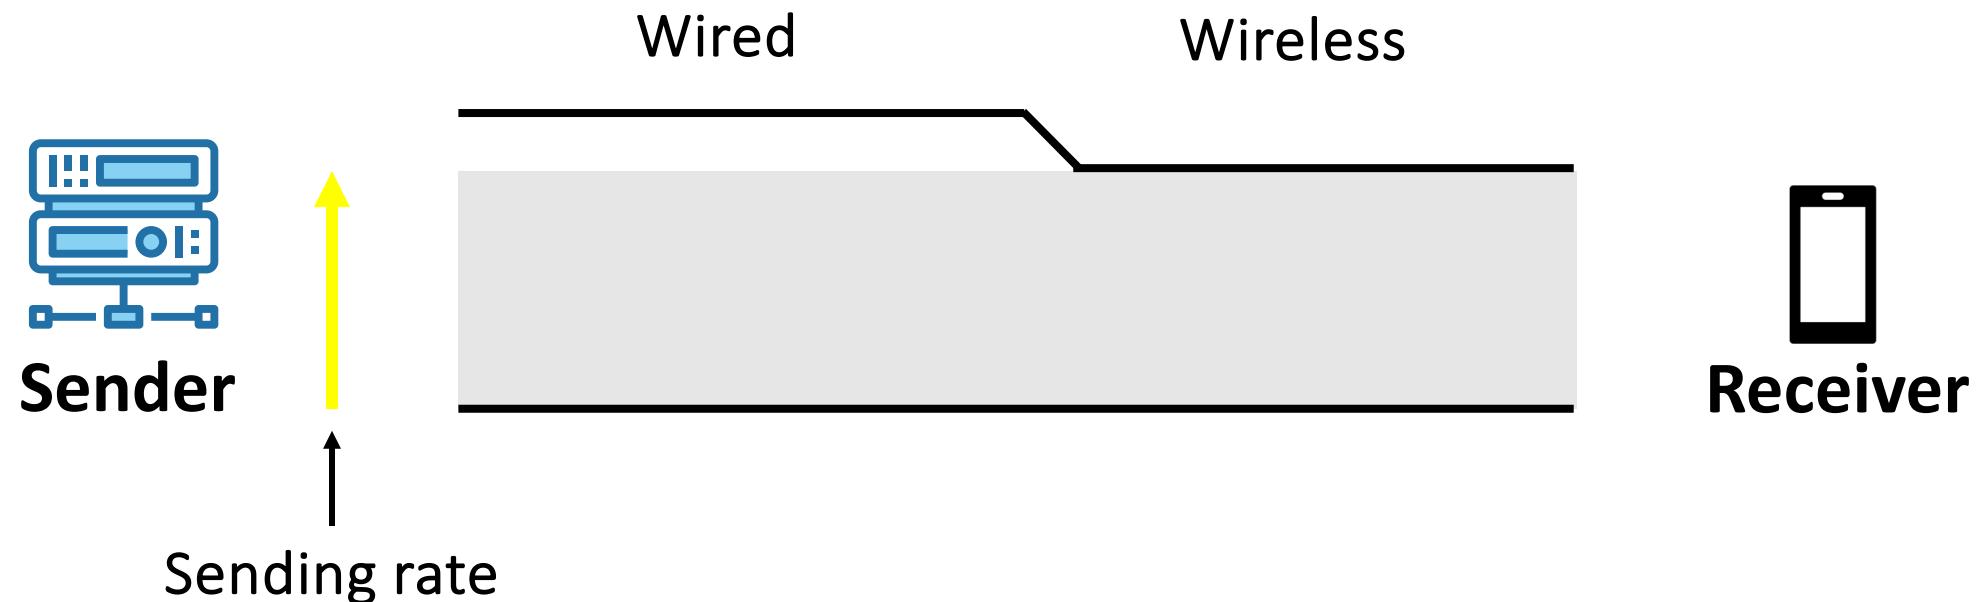

Sending rate determines the final achieved end-to-end link throughput

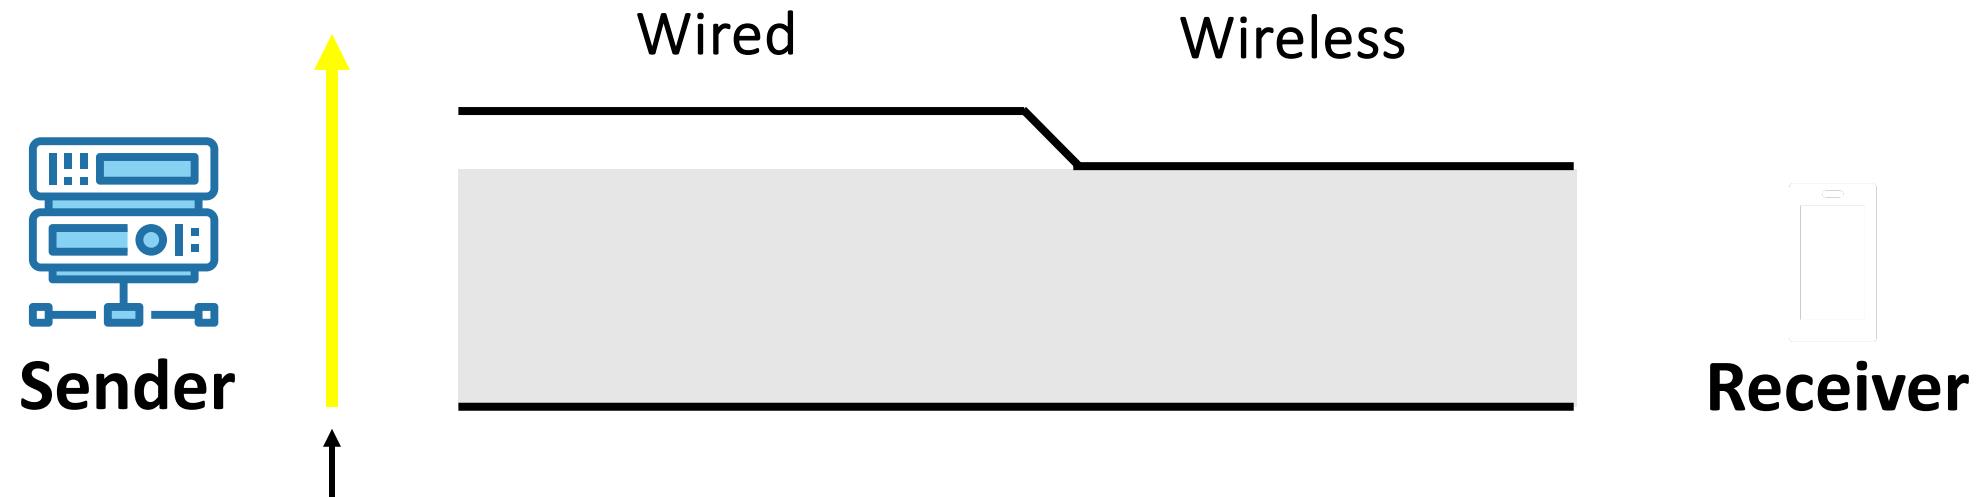

# Sending rate determines the achieved throughput

# Sending rate determines the achieved throughput

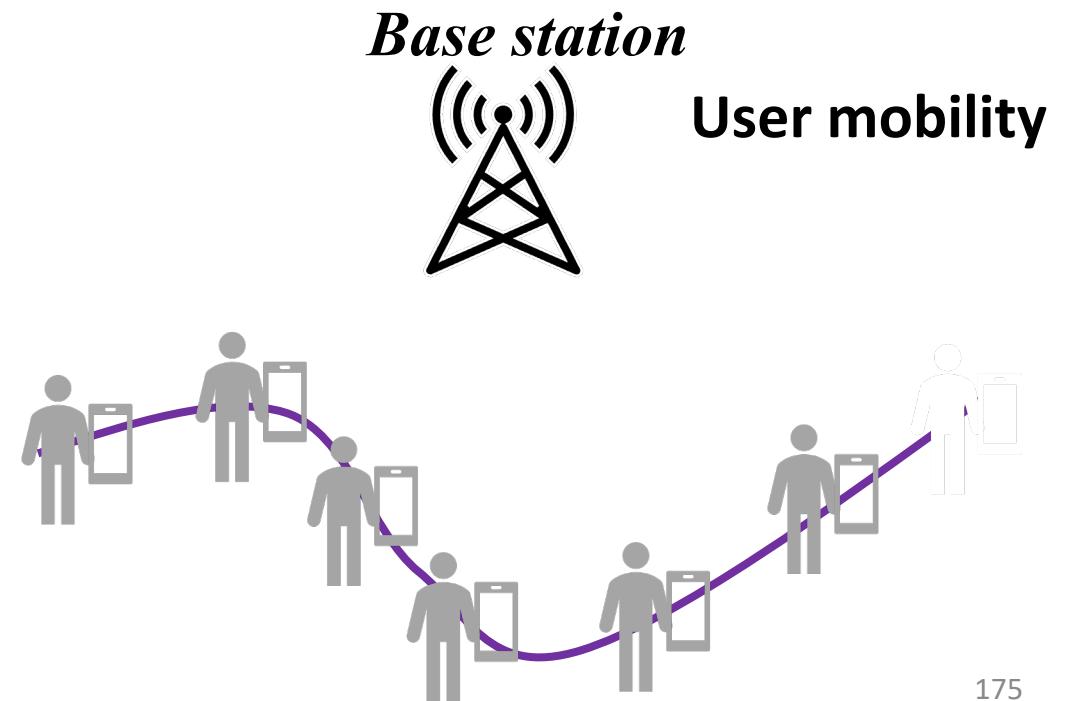

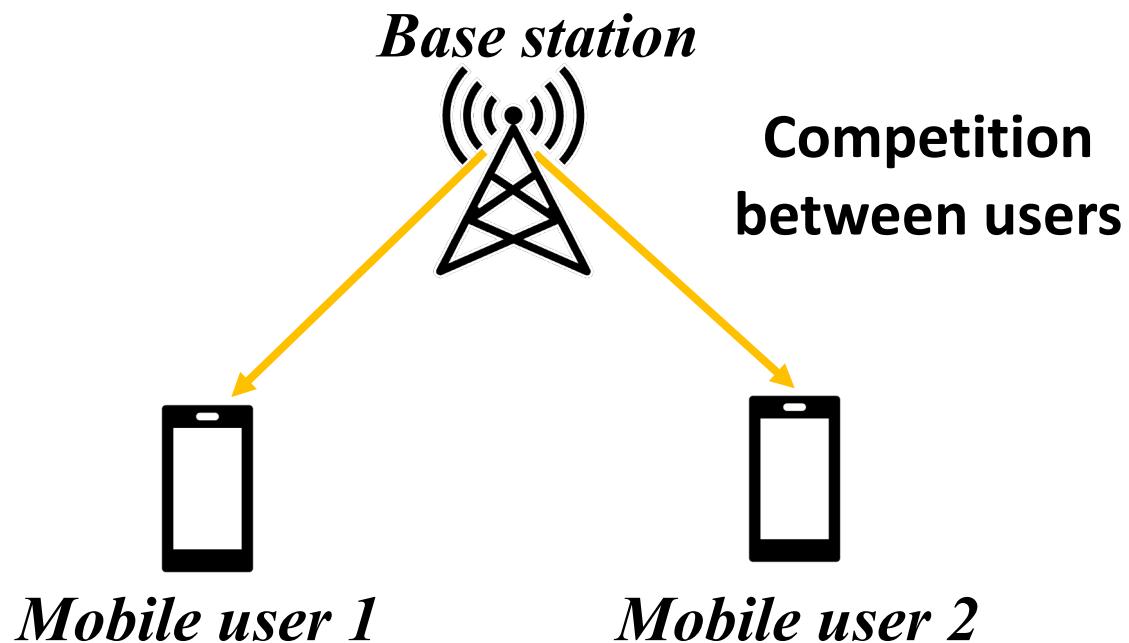

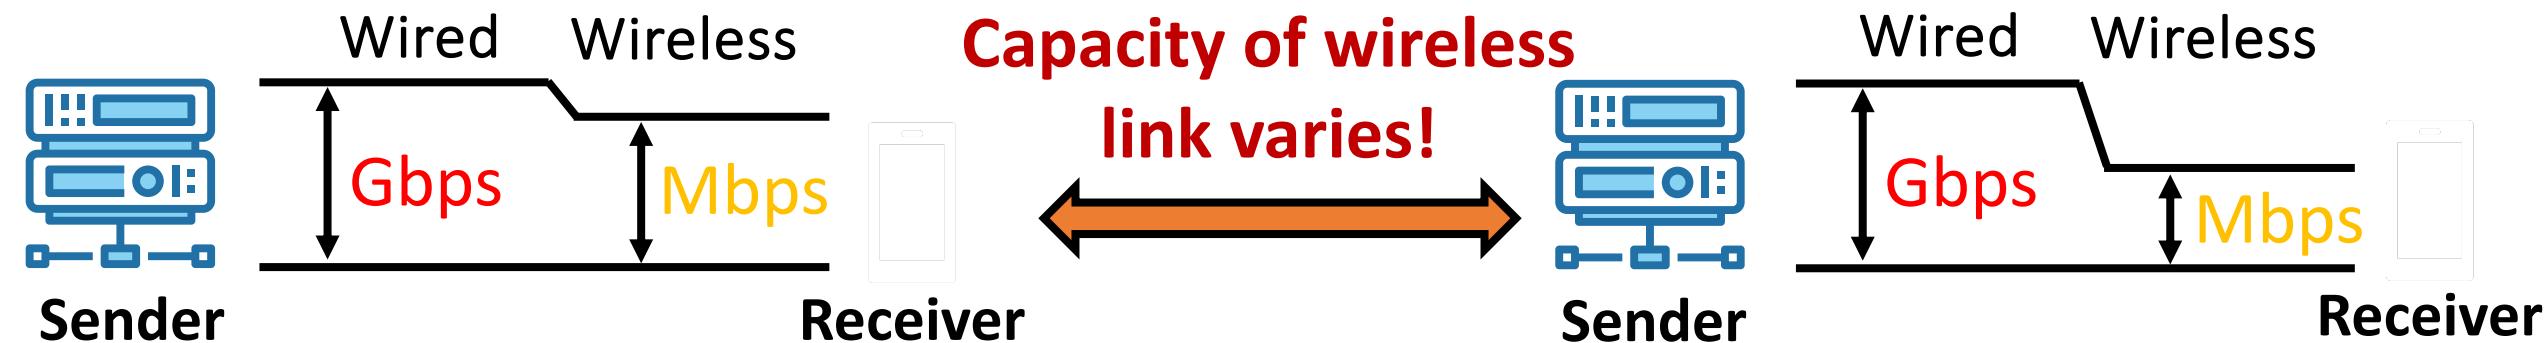

# Sending rate determines the achieved throughput

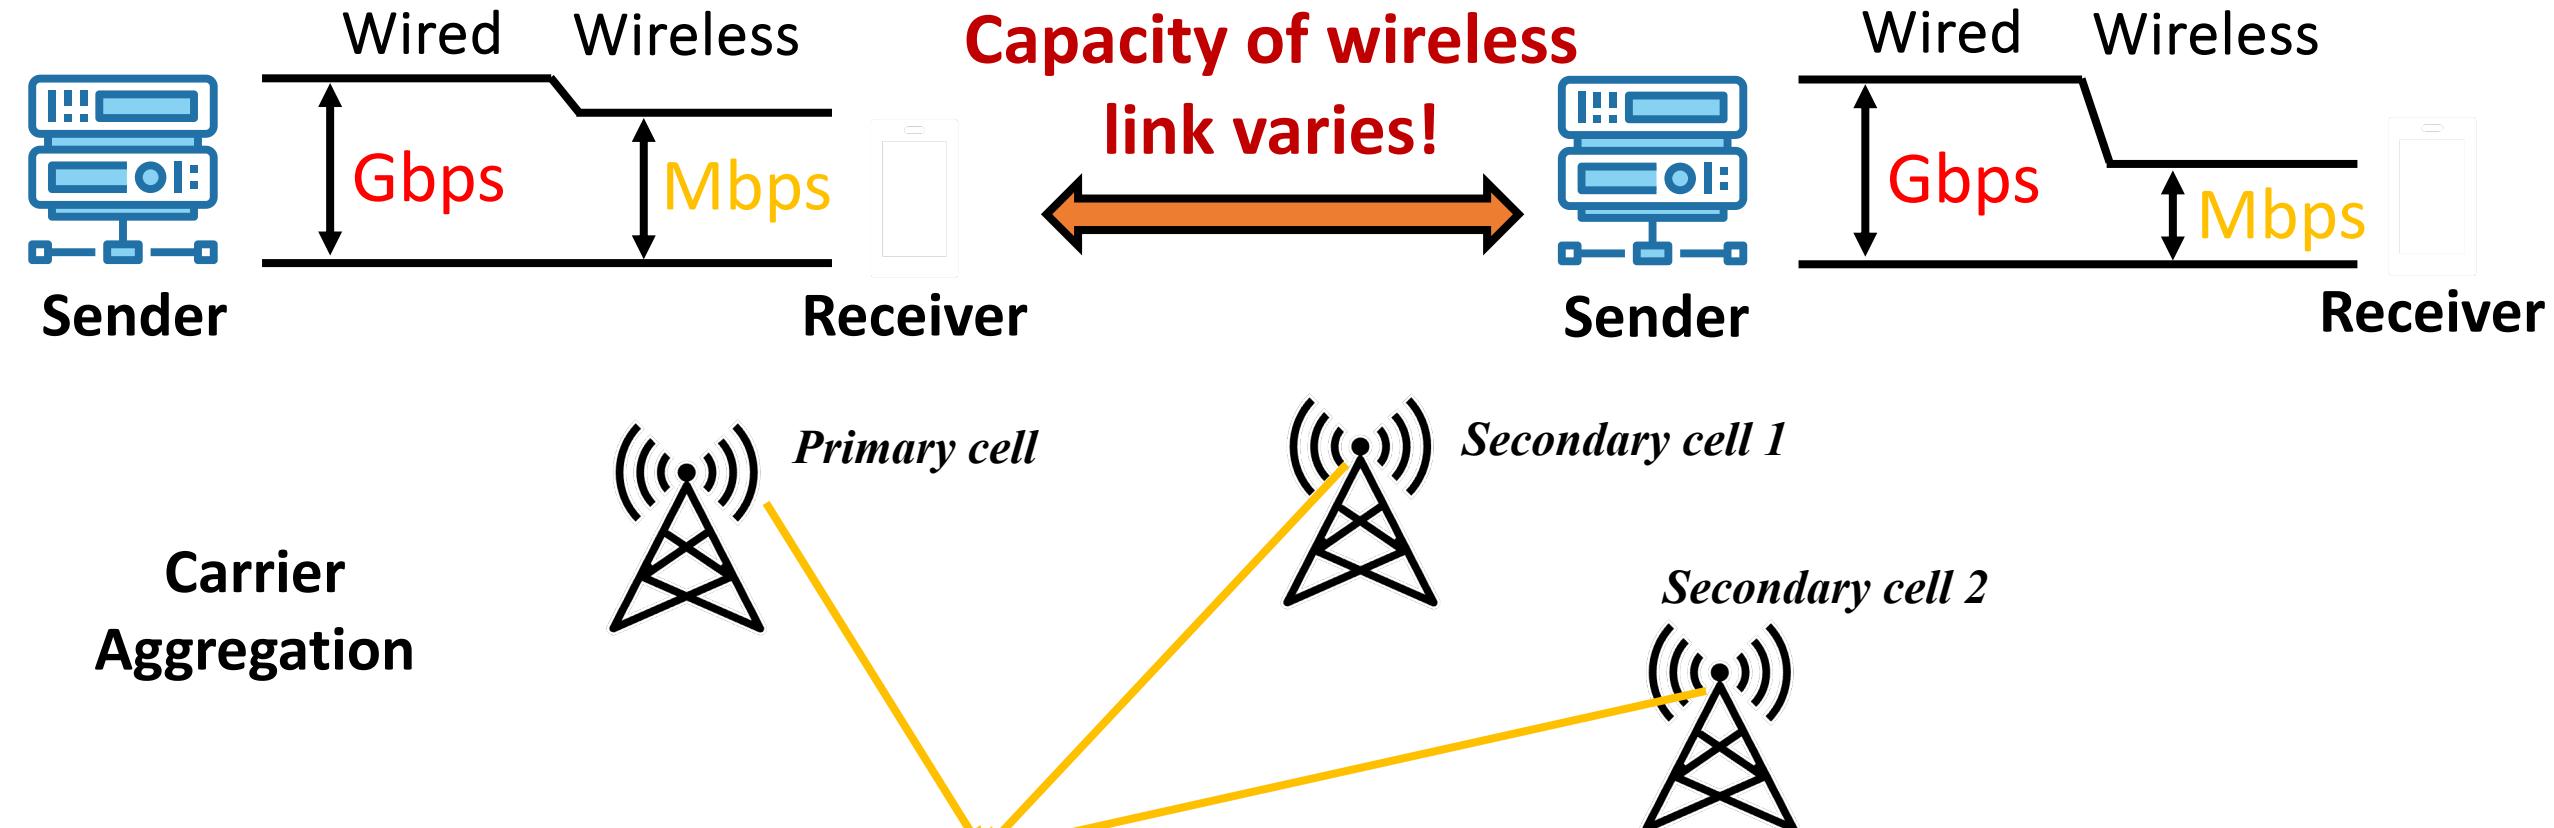

We need to a congestion control algorithm to match the sending rate to the capacity of the bottleneck!

# End-to-end congestion control is challenging for cellular networks

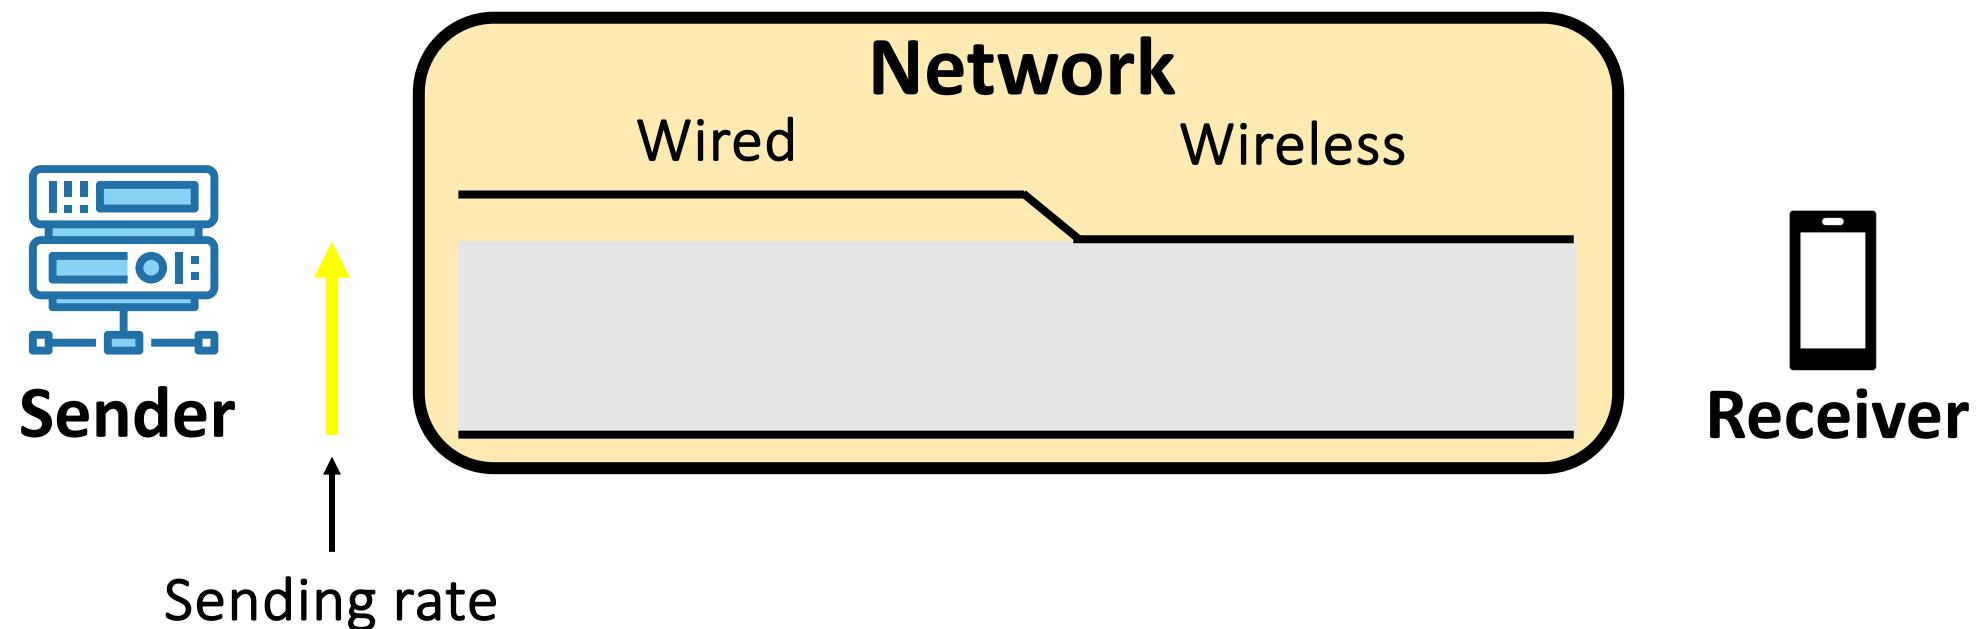

# Estimating the capacity of the wireless cellular link is challenging!

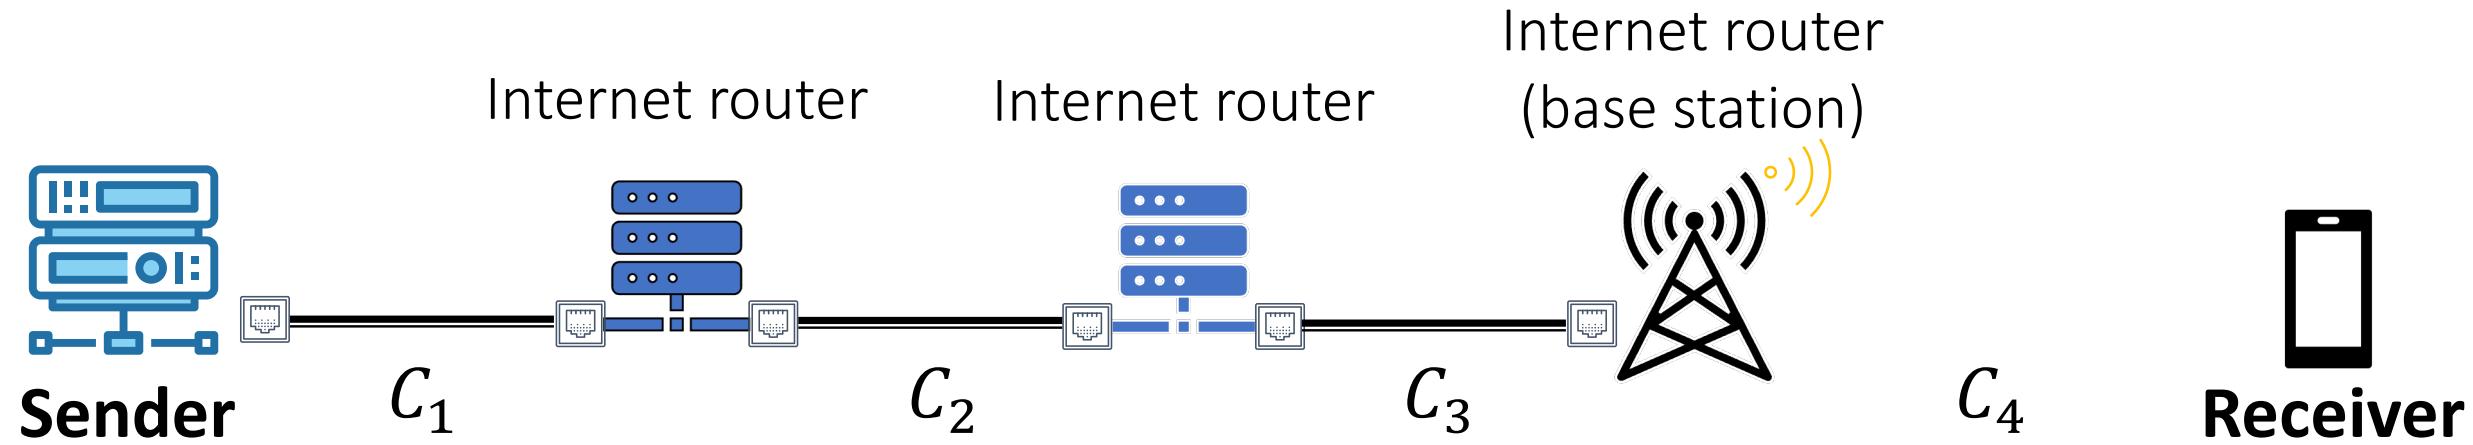

How does the current TCP congestion control algorithm estimate the bottleneck capacity?

# Type 1: Endpoints cooperate with the network

# Type 1: Endpoints cooperate with the network. Estimating the bottleneck capacity with full knowledge of all the routers inside the network

$$\text{Bottleneck capacity: } C_b = \min(C_1, C_2, C_3, C_4)$$

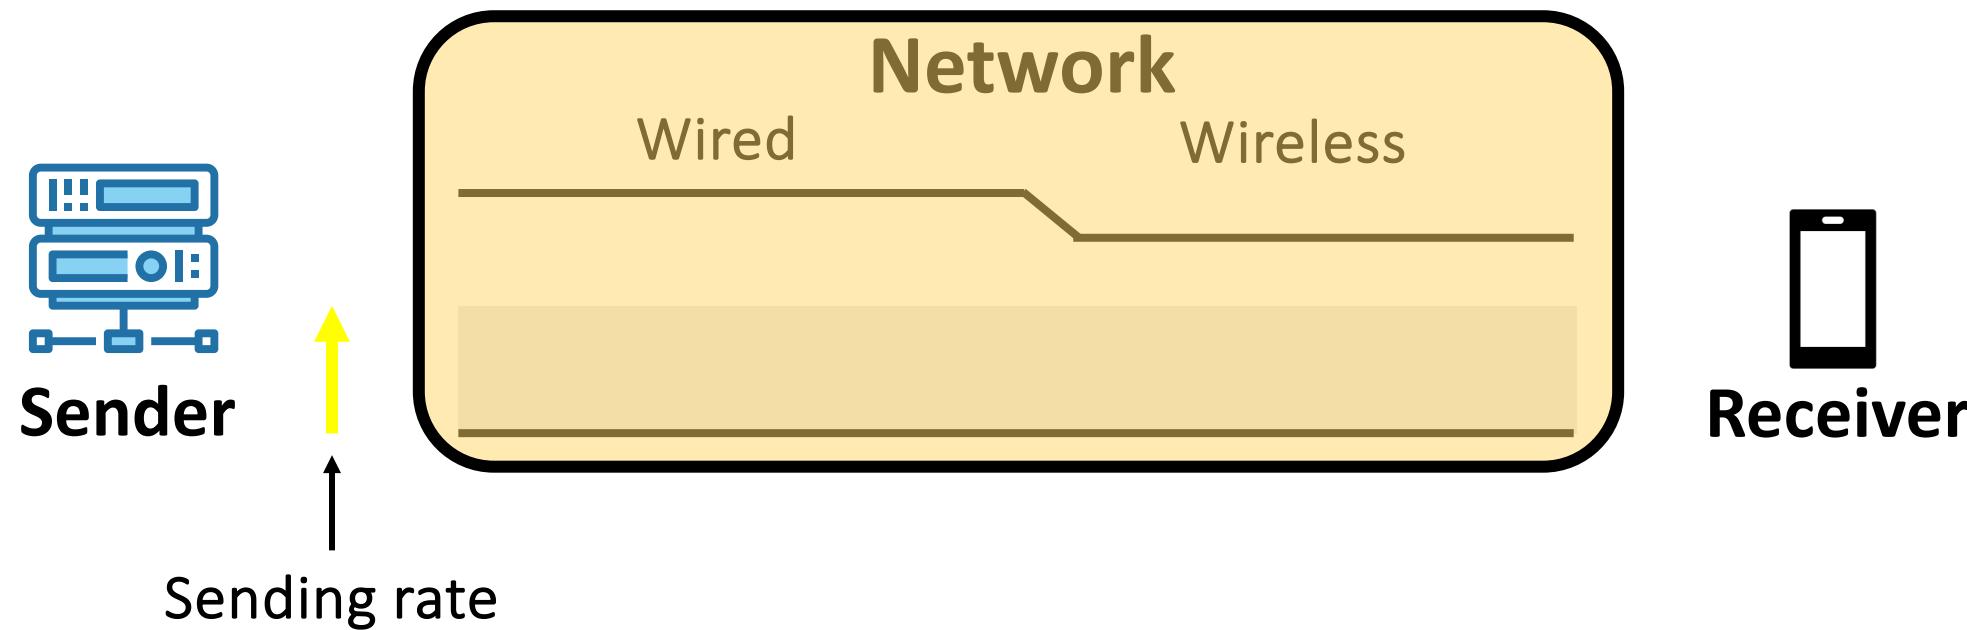

Pros:

- Accurate capacity estimation
- Reactive to channel dynamics

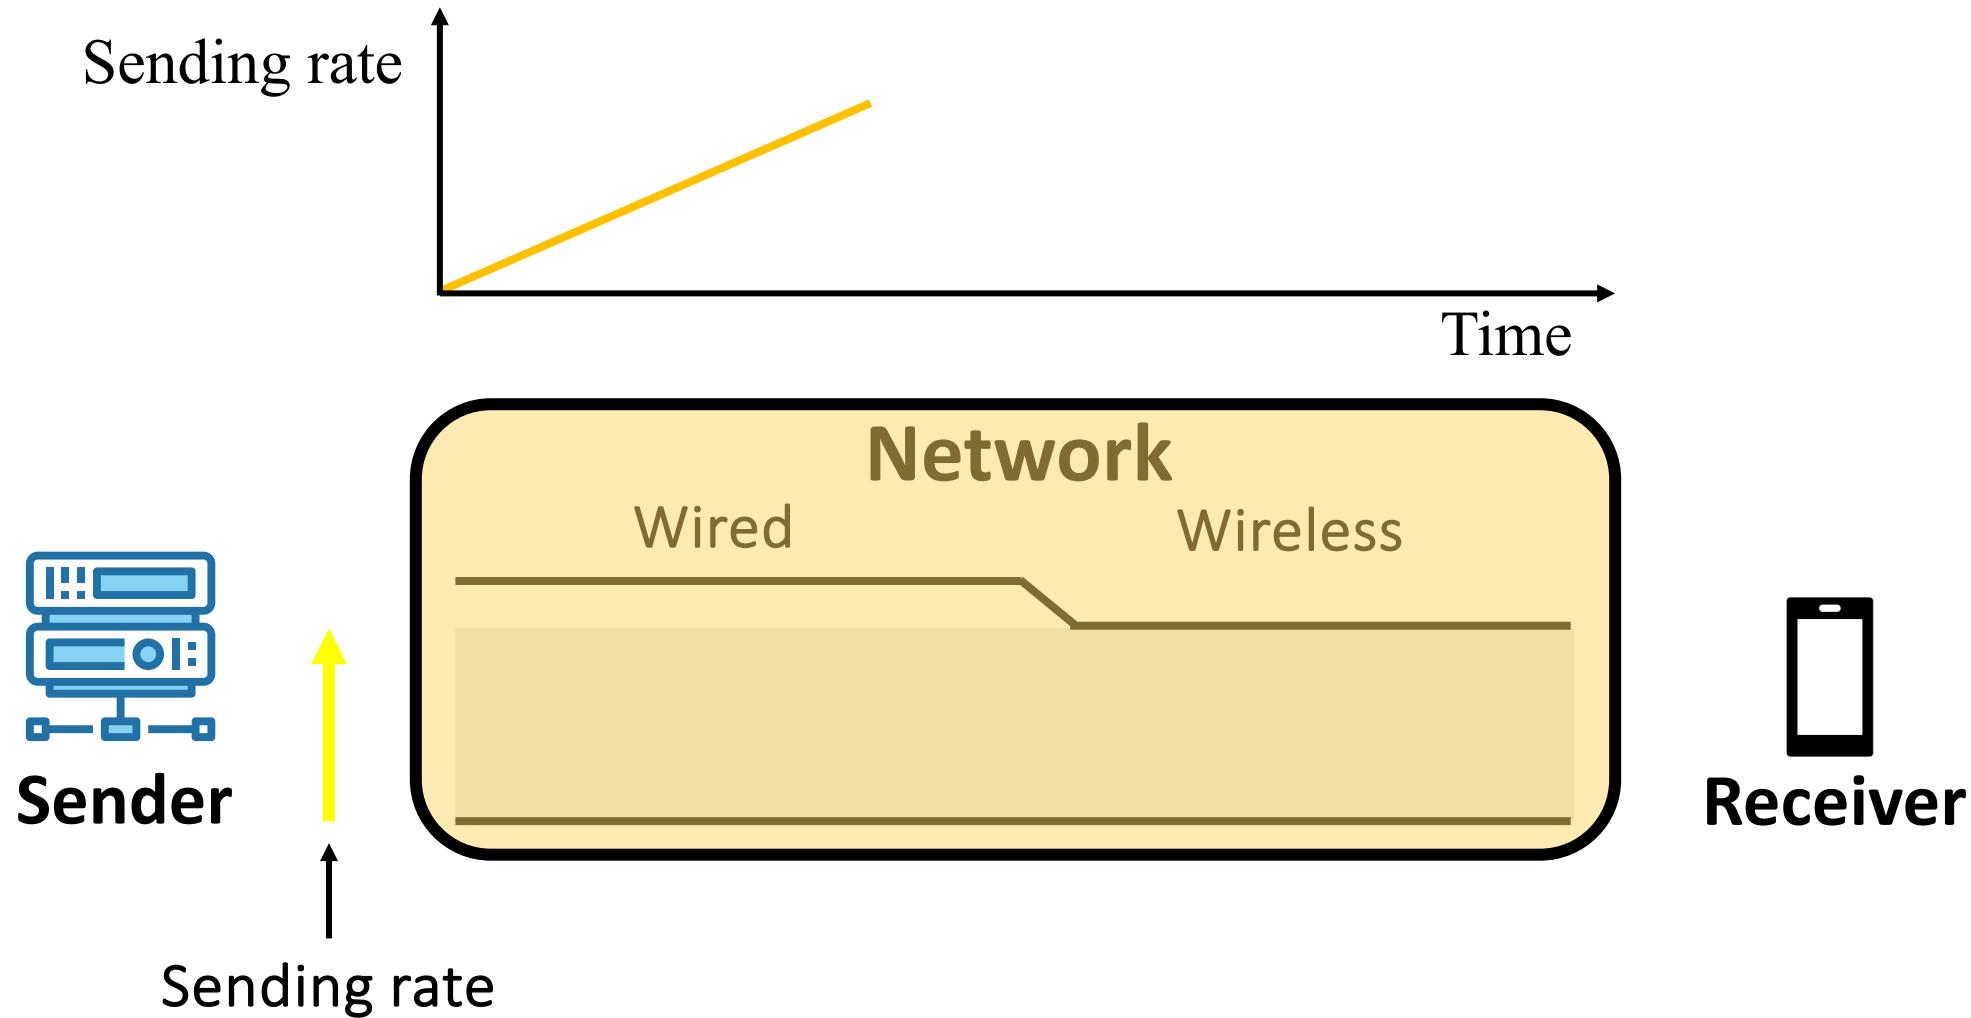

Cons

- Deployment cost

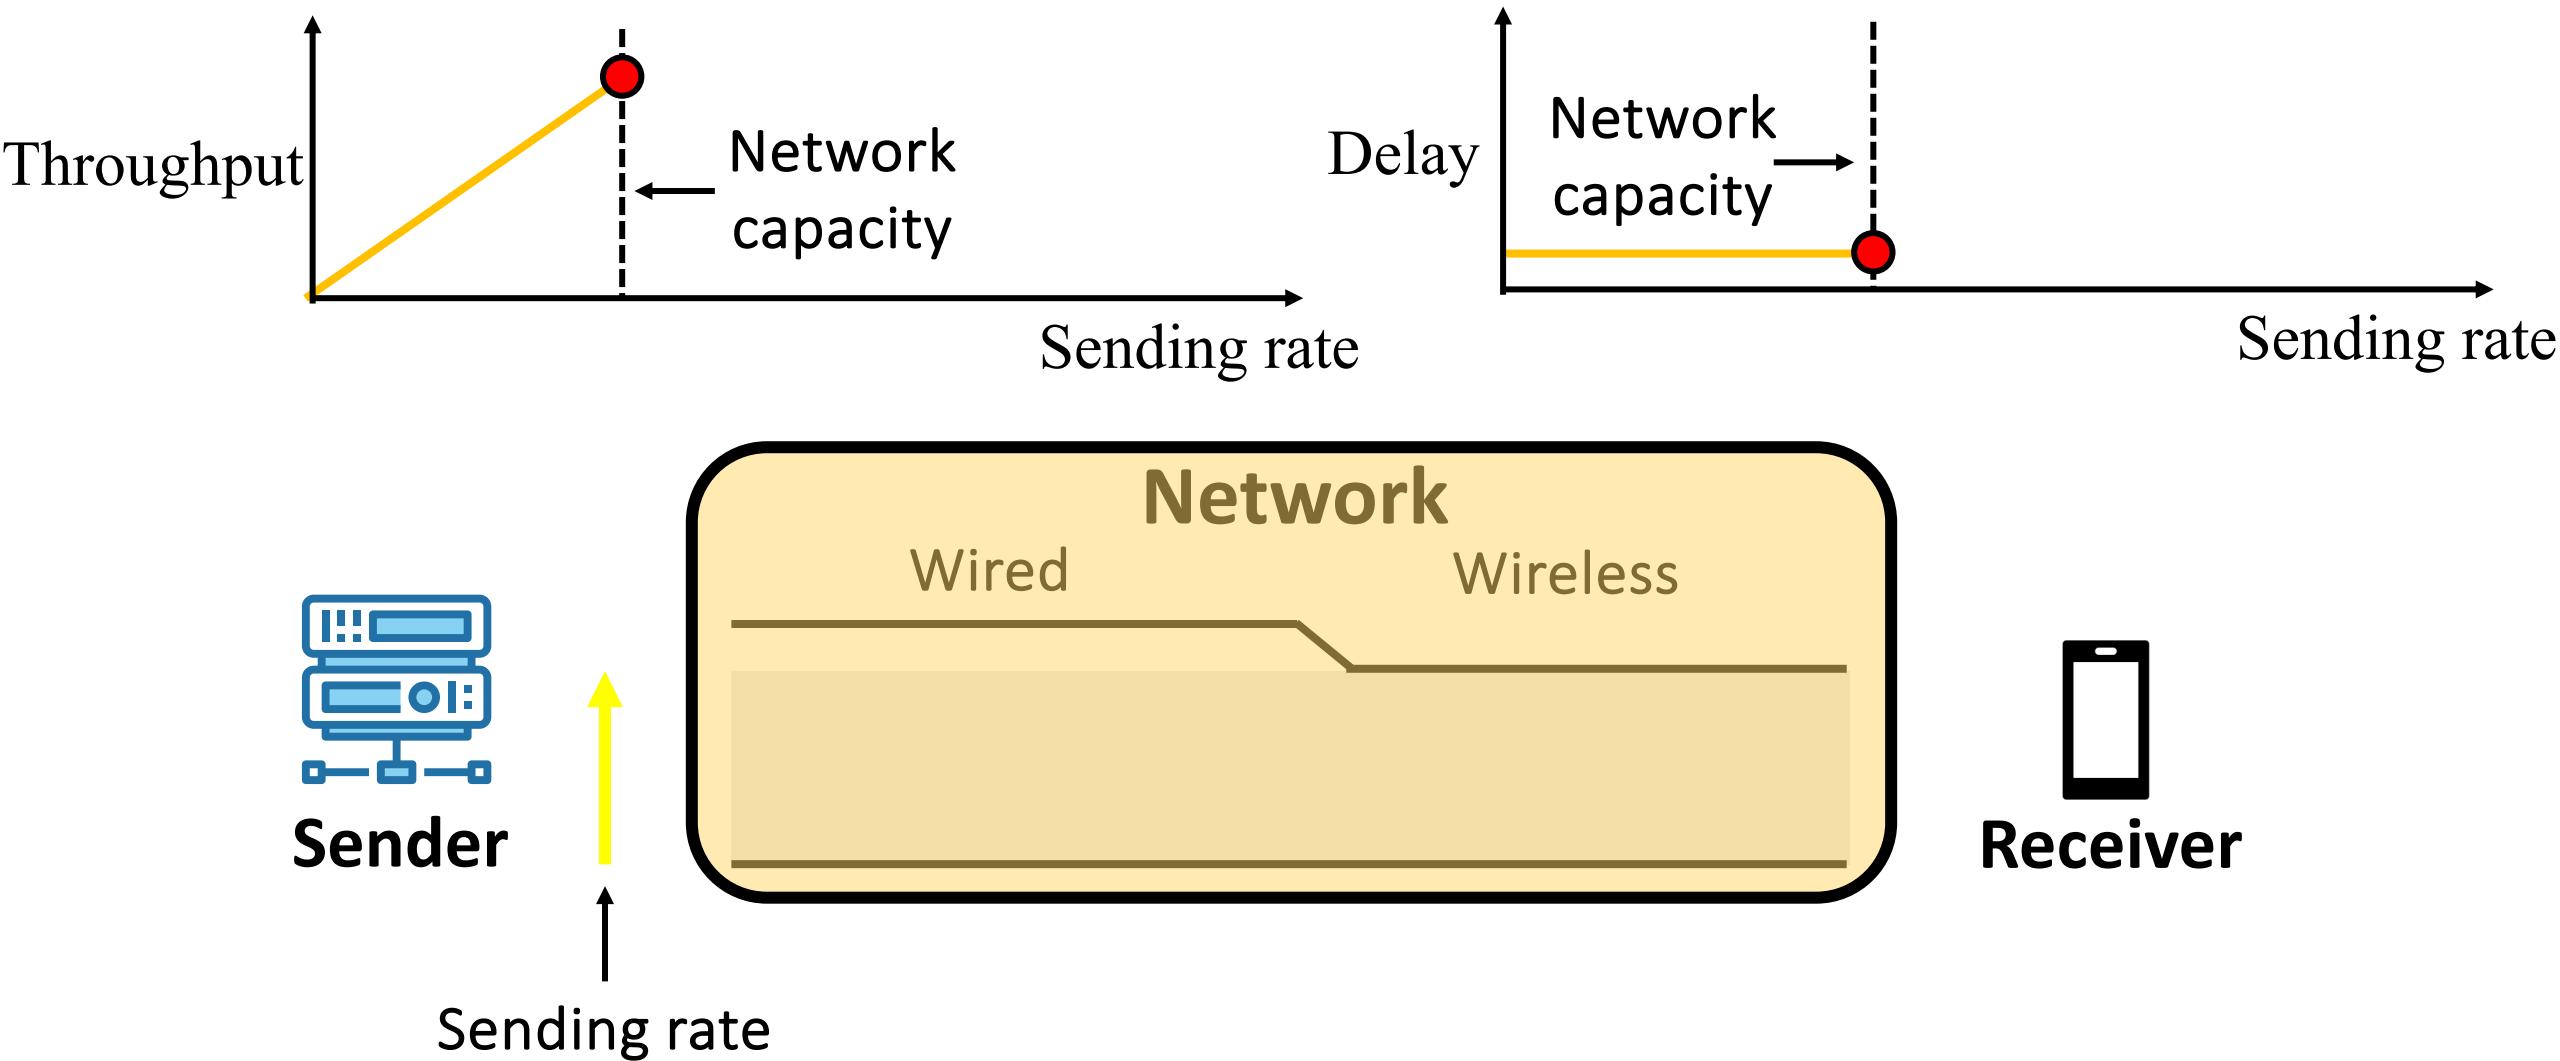

# Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

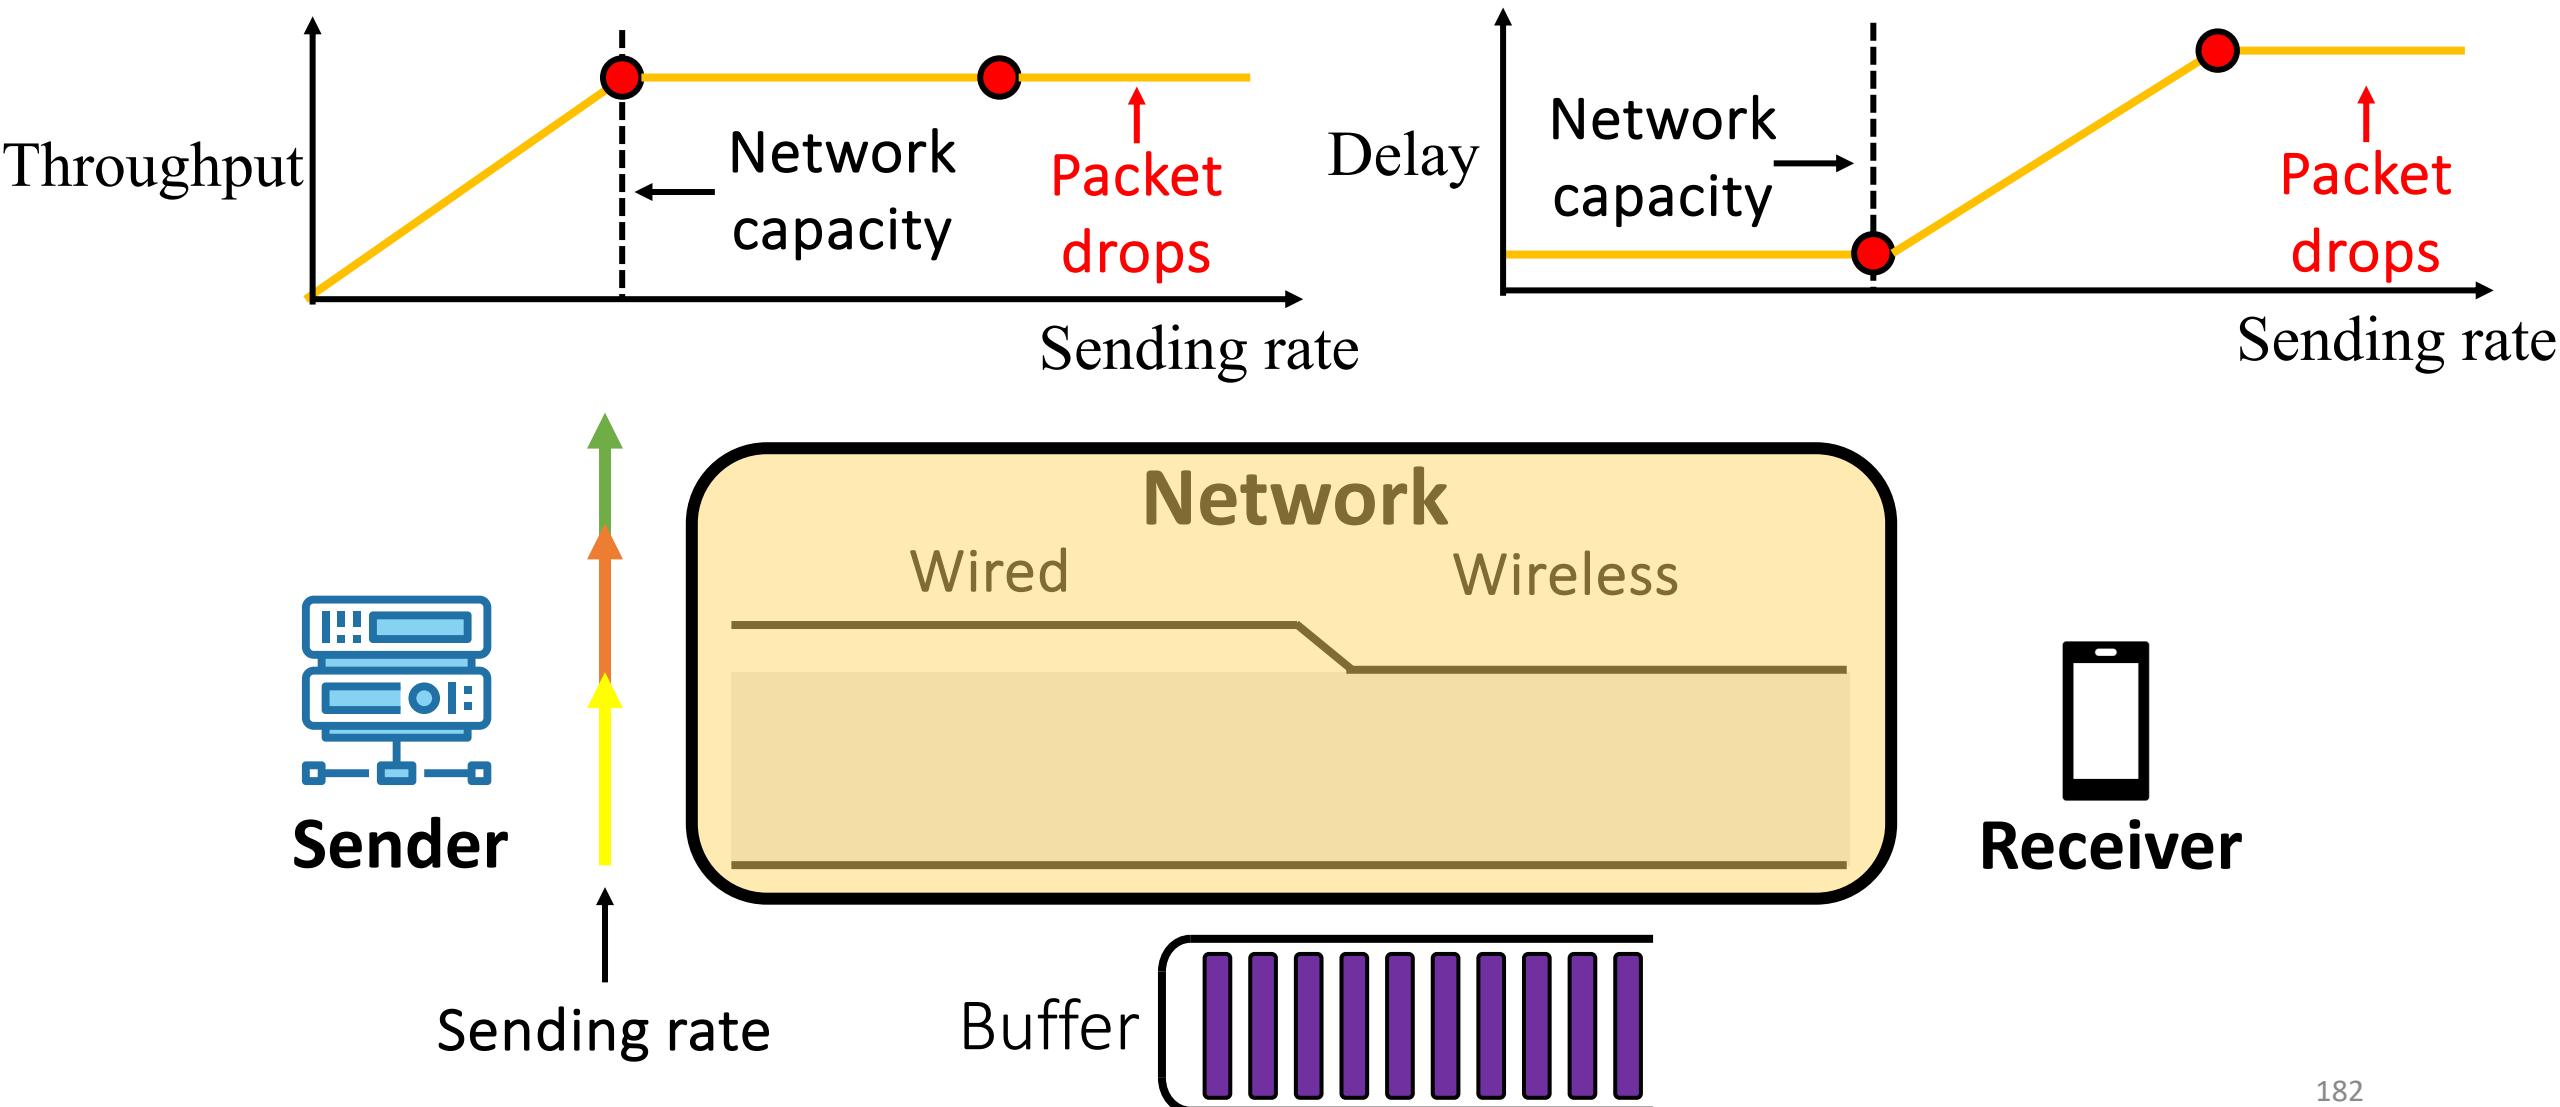

# Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

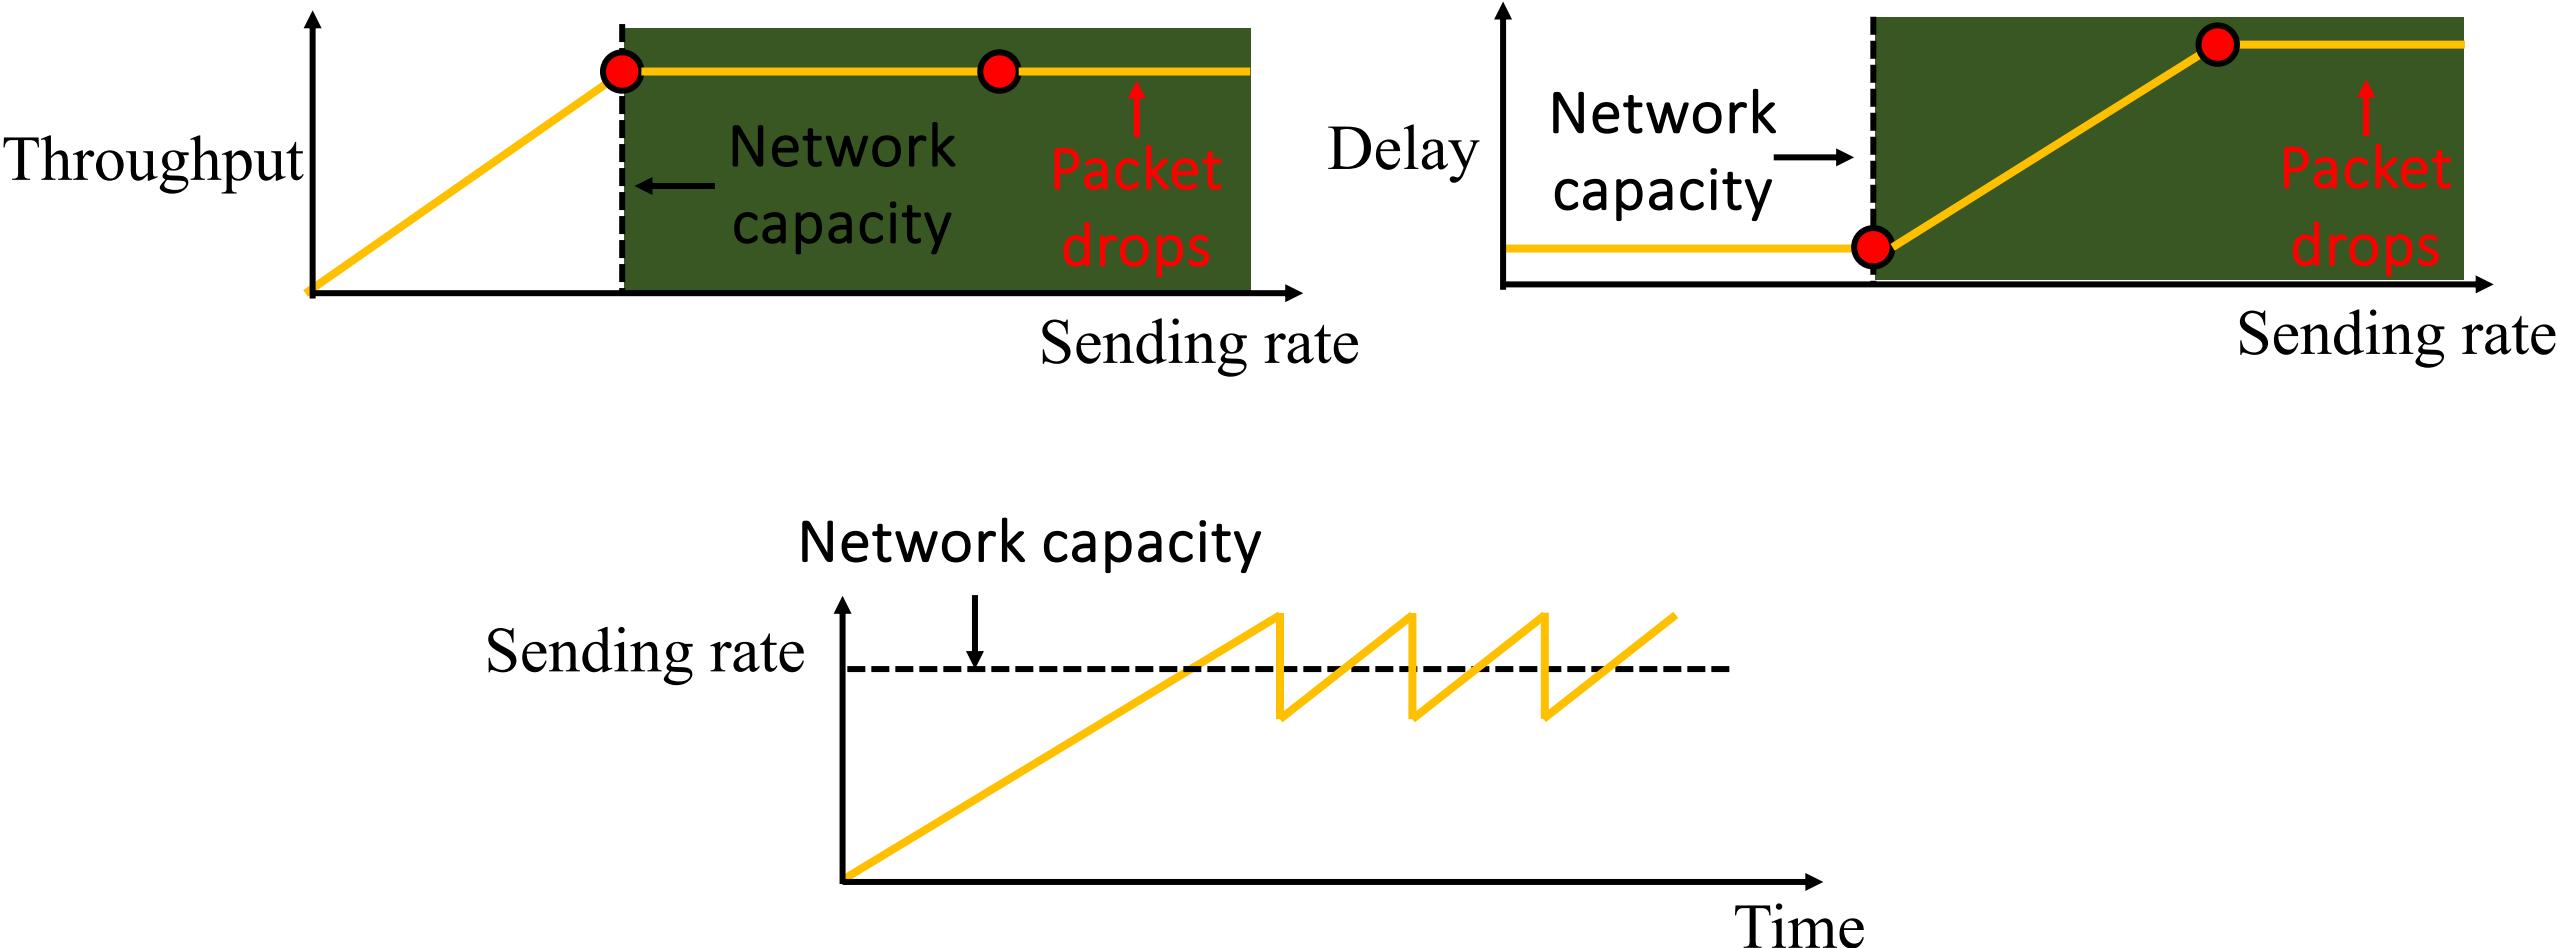

## Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

## Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

## Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

# TCP congestion control: AIMD

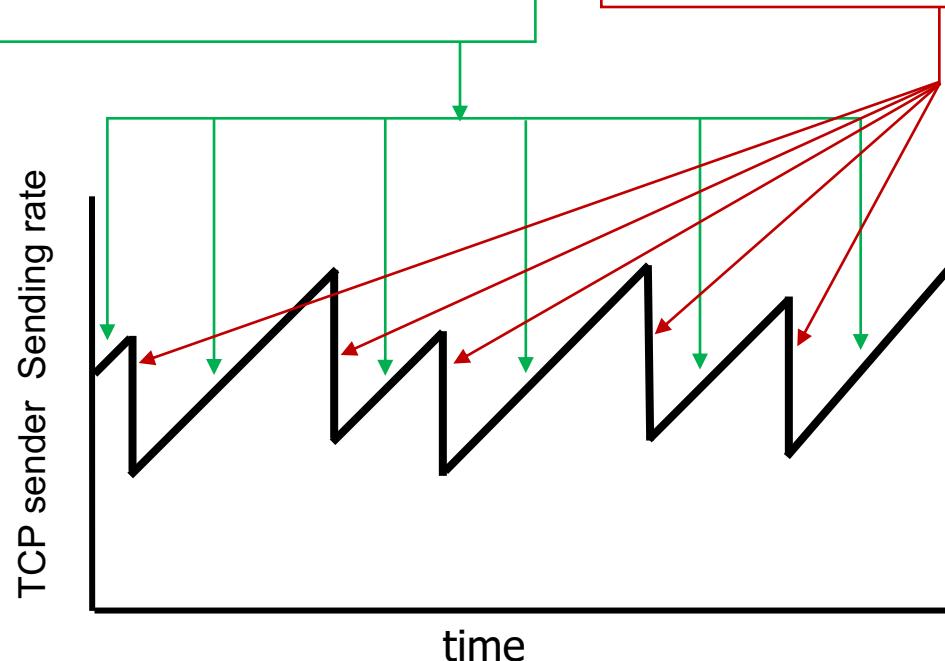

- *approach:* senders can increase sending rate until packet loss (congestion) occurs, then decrease sending rate on loss event

## Additive Increase

increase sending rate by 1 maximum segment size every RTT until loss detected

## Multiplicative Decrease

cut sending rate in half at each loss event

**AIMD** sawtooth behavior: *probing* for bandwidth

# TCP AIMD: more

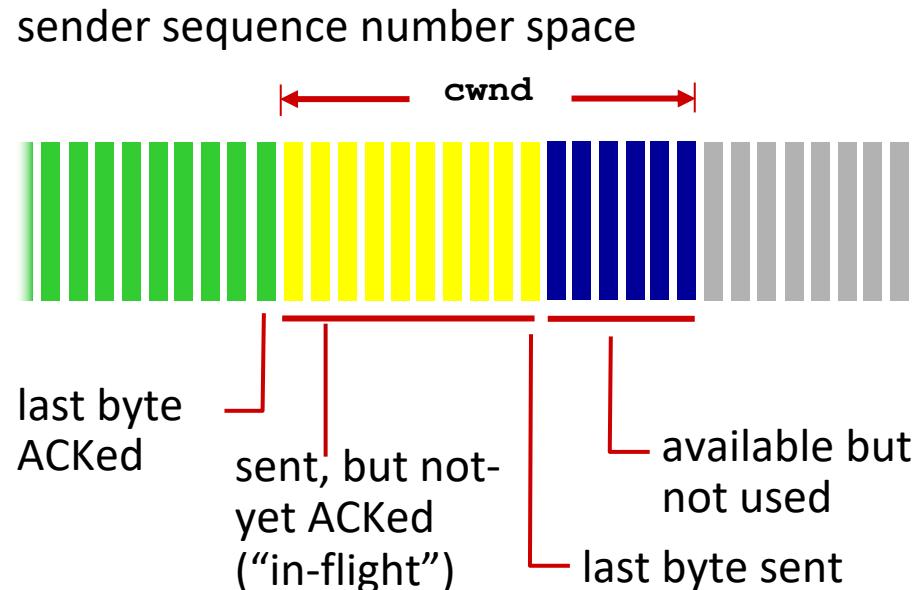

*Multiplicative decrease* detail: sending rate is

- Cut in half on loss detected by triple duplicate ACK (TCP Reno)
- Cut to 1 MSS (maximum segment size) when loss detected by timeout (TCP Tahoe)

Why AIMD?

- AIMD – a distributed, asynchronous algorithm – has been shown to:
  - optimize congested flow rates network wide!
  - have desirable stability properties

# TCP congestion control: details

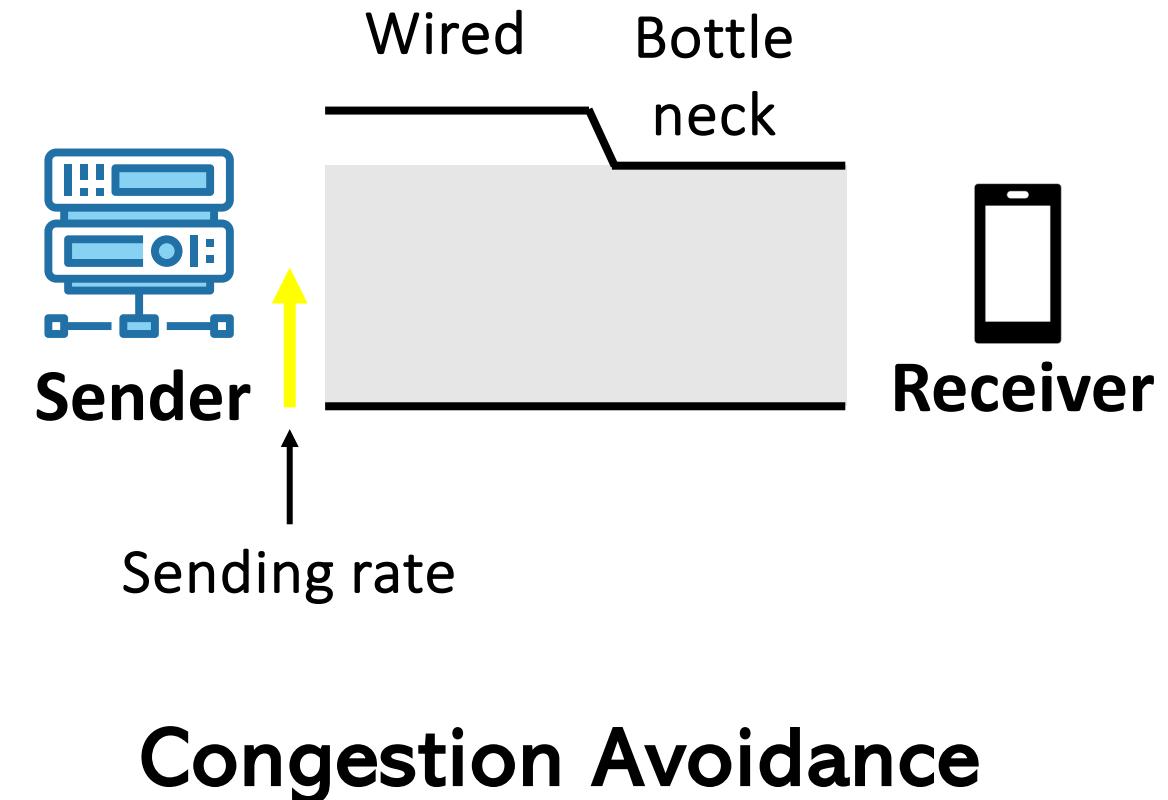

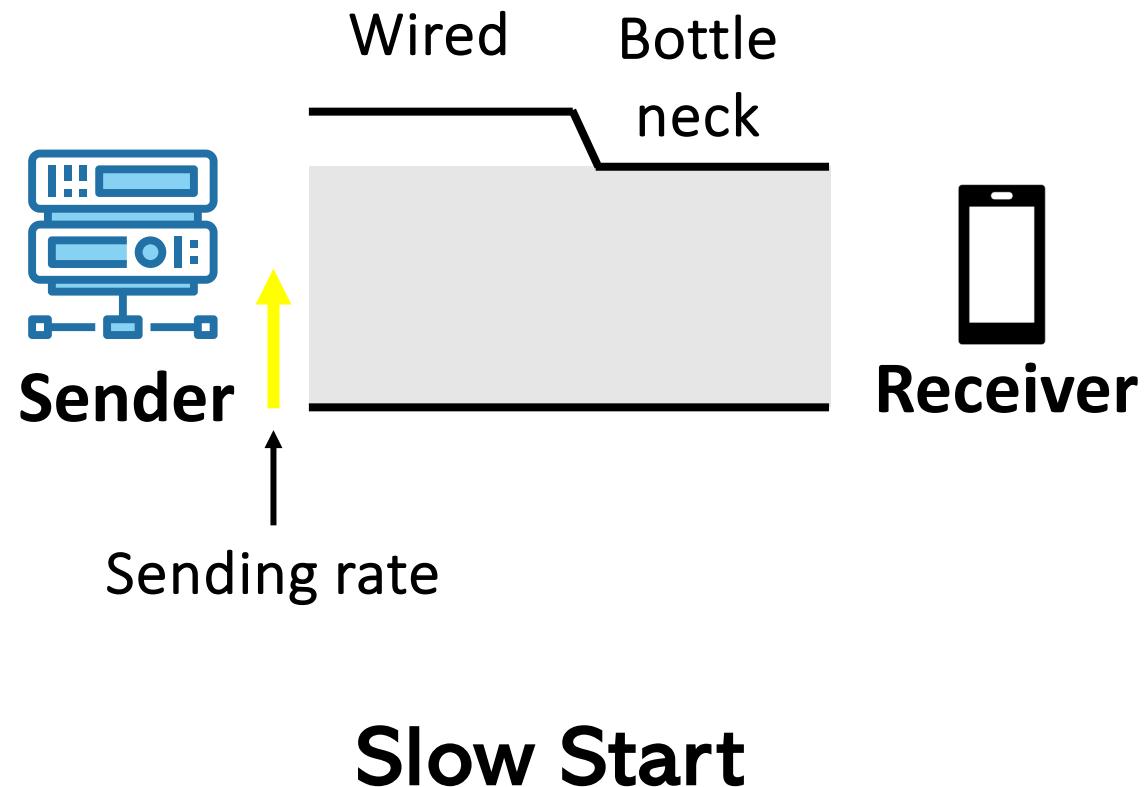

TCP sending behavior:

- *roughly*: send  $cwnd$  bytes, wait RTT for ACKS, then send more bytes

$$\text{TCP rate} \approx \frac{cwnd}{RTT} \text{ bytes/sec}$$

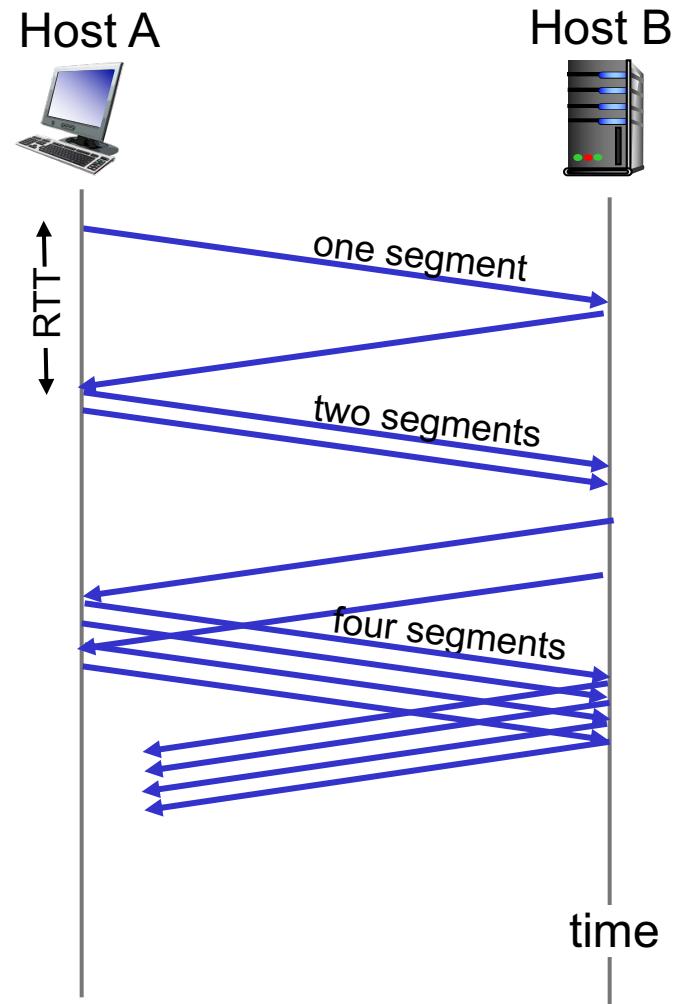

- TCP sender limits transmission:  $\text{LastByteSent} - \text{LastByteAcked} \leq cwnd$
- $cwnd$  is dynamically adjusted in response to observed network congestion (implementing TCP congestion control)

# Two Stage of TCP: Slow-Start and Congestion avoidance

# TCP slow start

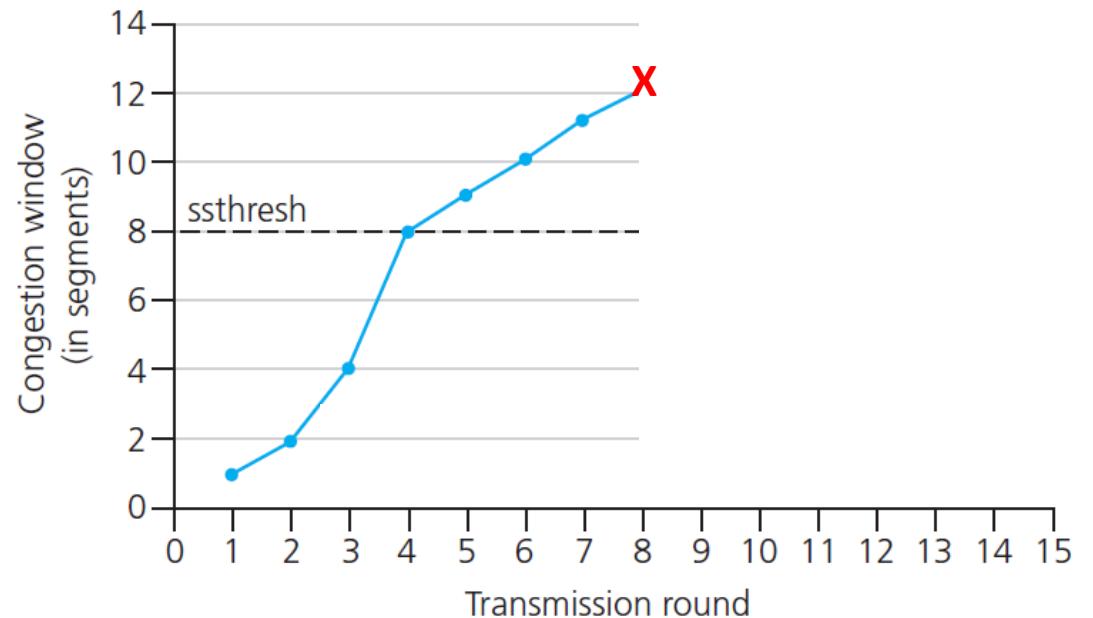

- when connection begins, increase rate exponentially until first loss event:
  - initially **cwnd** = 1 MSS
  - double **cwnd** every RTT
  - done by incrementing **cwnd** for every ACK received
- *summary:* initial rate is slow, but ramps up exponentially fast

# TCP: from slow start to congestion avoidance

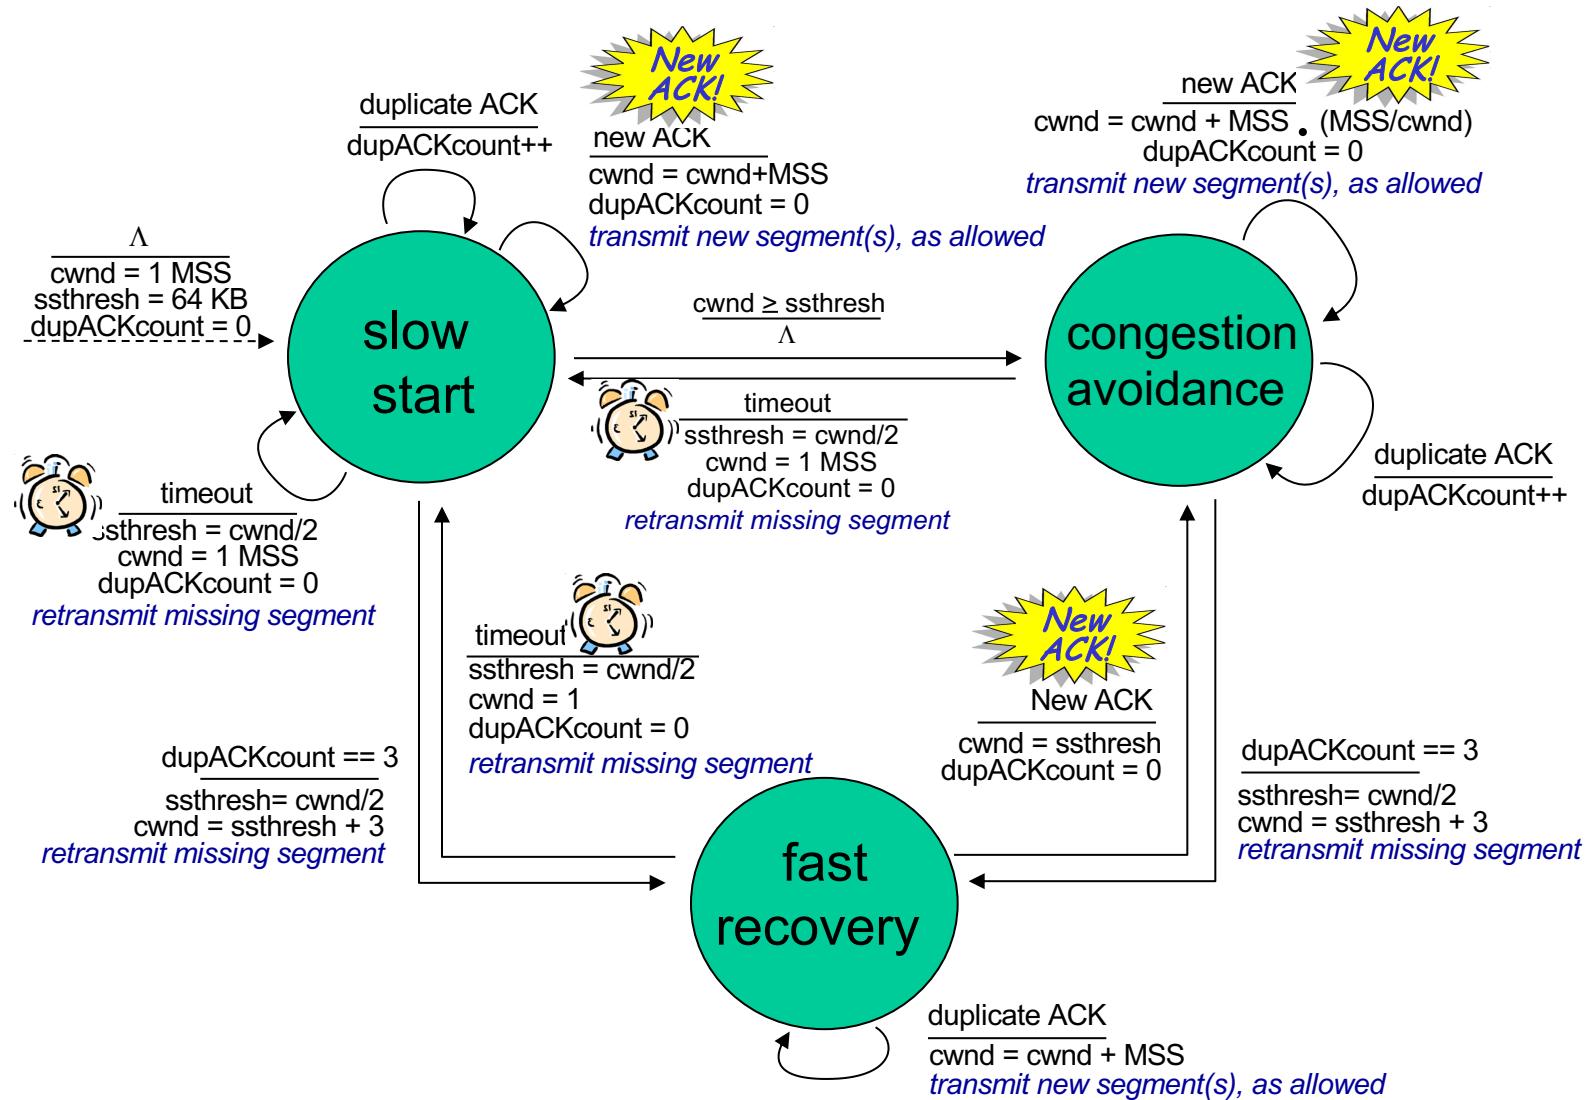

**Q:** when should the exponential increase switch to linear?

**A:** when **cwnd** gets to 1/2 of its value before timeout.

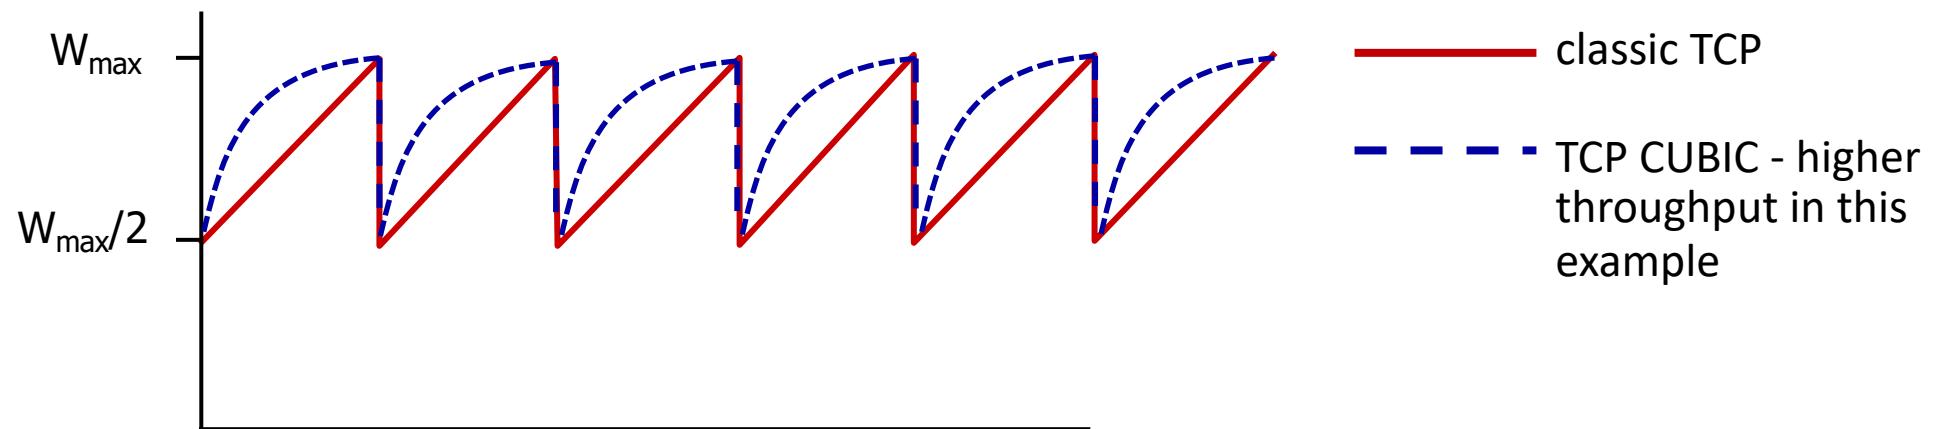

\* Check out the online interactive exercises for more examples: [http://gaia.cs.umass.edu/kurose\\_ross/interactive/](http://gaia.cs.umass.edu/kurose_ross/interactive/)

# Summary: TCP congestion control

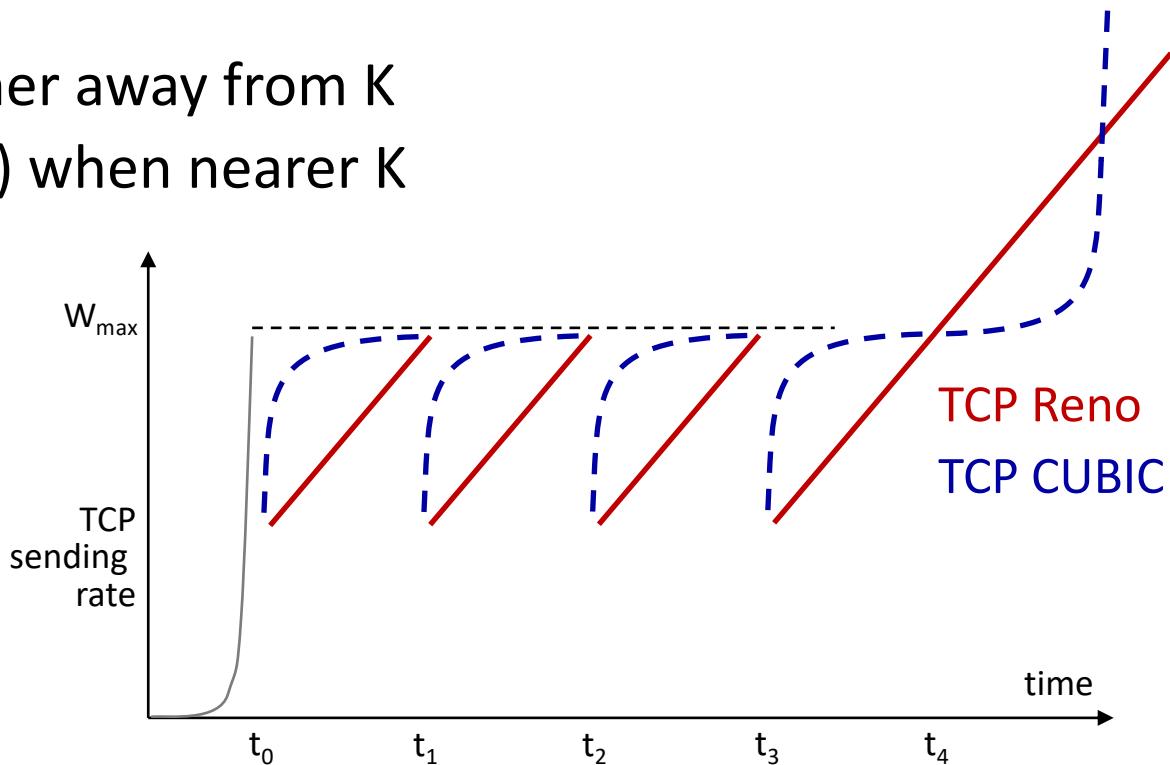

# TCP CUBIC

- Is there a better way than AIMD to “probe” for usable bandwidth?
- Insight/intuition:
  - $W_{\max}$ : sending rate at which congestion loss was detected
  - congestion state of bottleneck link probably (?) hasn’t changed much
  - after cutting rate/window in half on loss, initially ramp to  $W_{\max}$  *faster*, but then approach  $W_{\max}$  more *slowly*

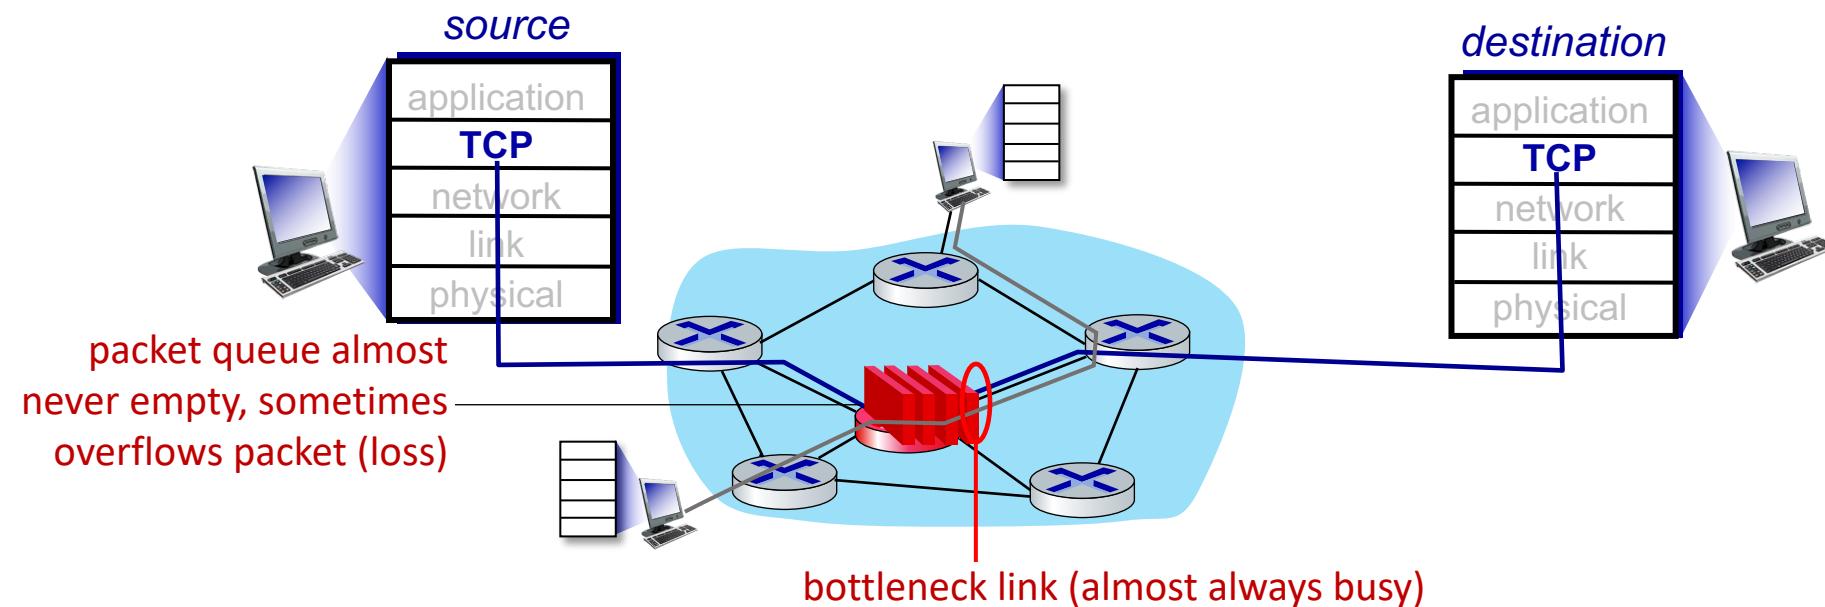

# TCP CUBIC

- K: point in time when TCP window size will reach  $W_{\max}$ 
  - K itself is tunable
- increase W as a function of the *cube* of the distance between current time and K
  - larger increases when further away from K
  - smaller increases (cautious) when nearer K
- TCP CUBIC default in Linux, most popular TCP for popular Web servers

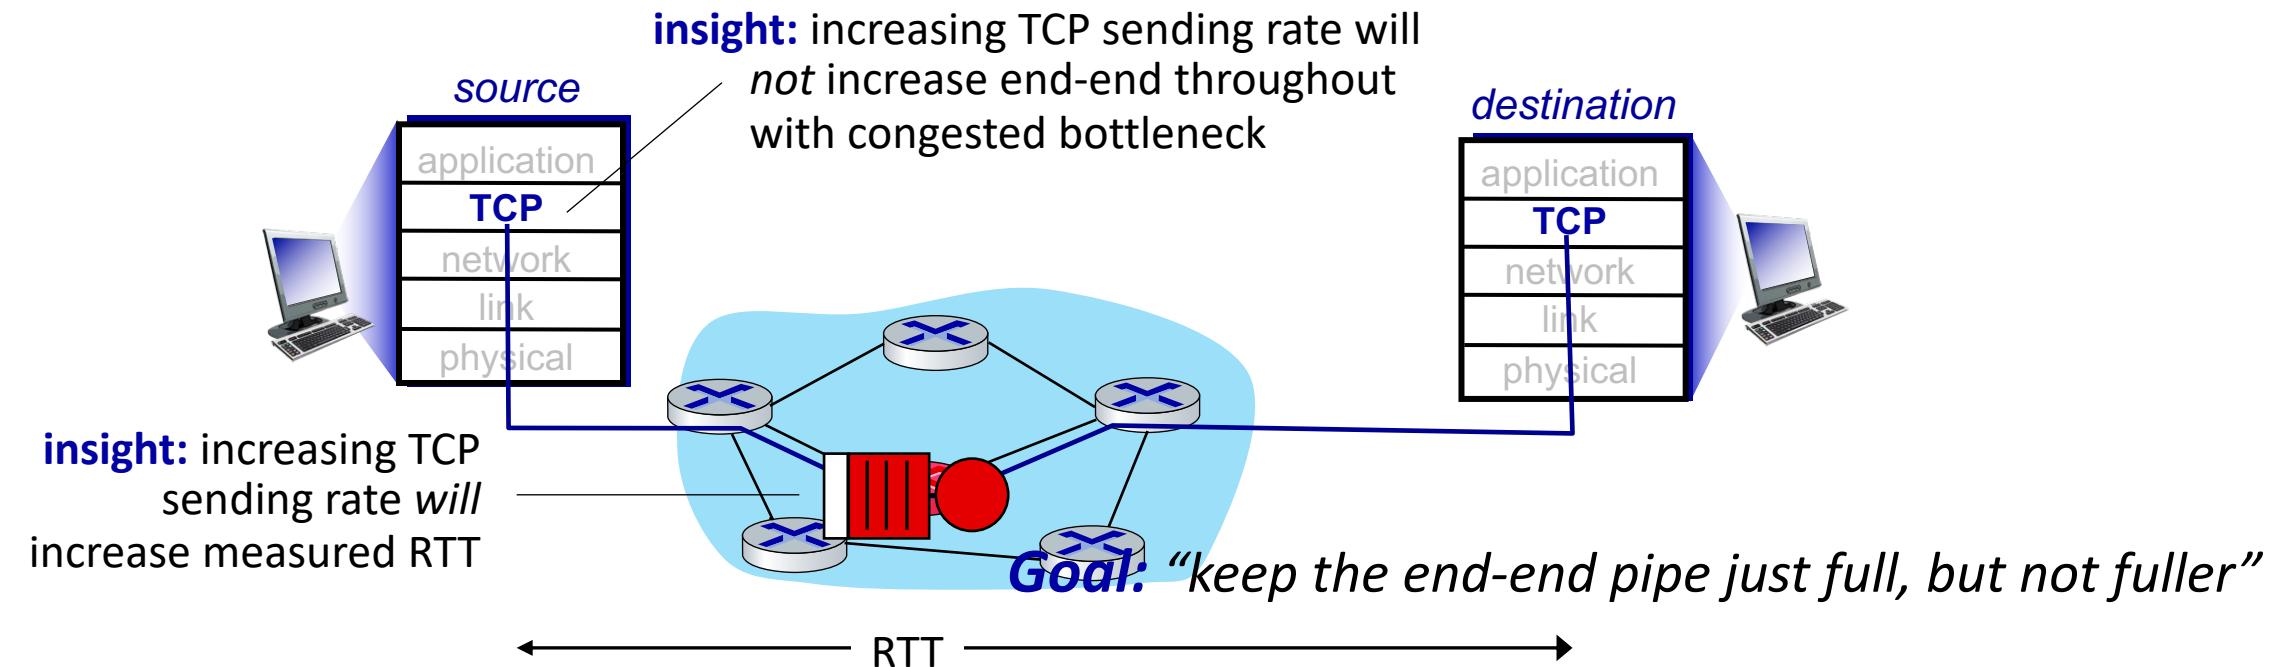

# TCP and the congested “bottleneck link”

- TCP (classic, CUBIC) increase TCP's sending rate until packet loss occurs at some router's output: the *bottleneck link*

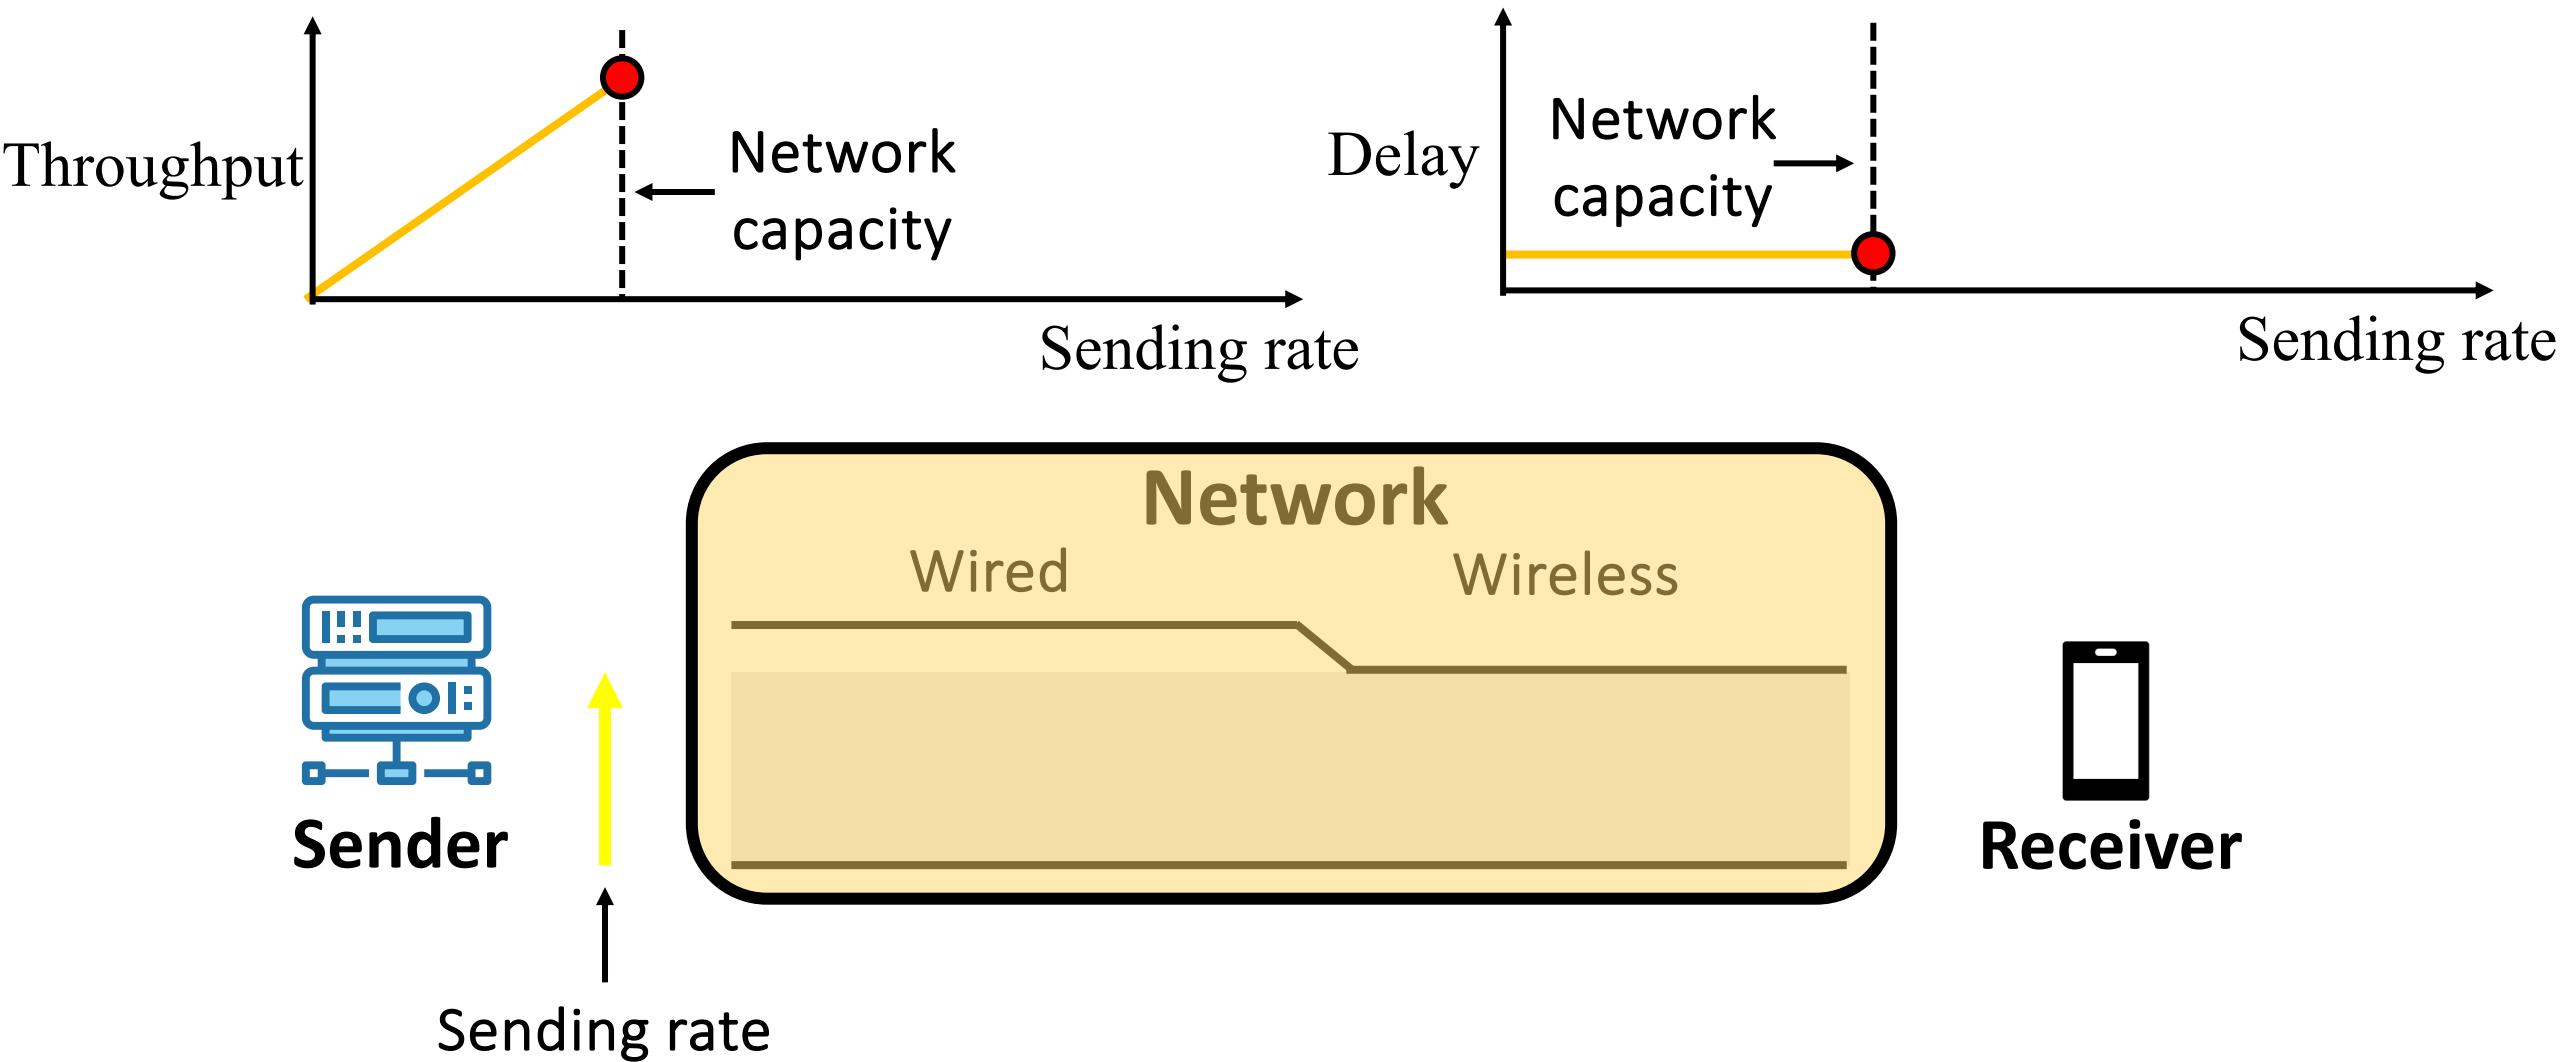

# TCP and the congested “bottleneck link”

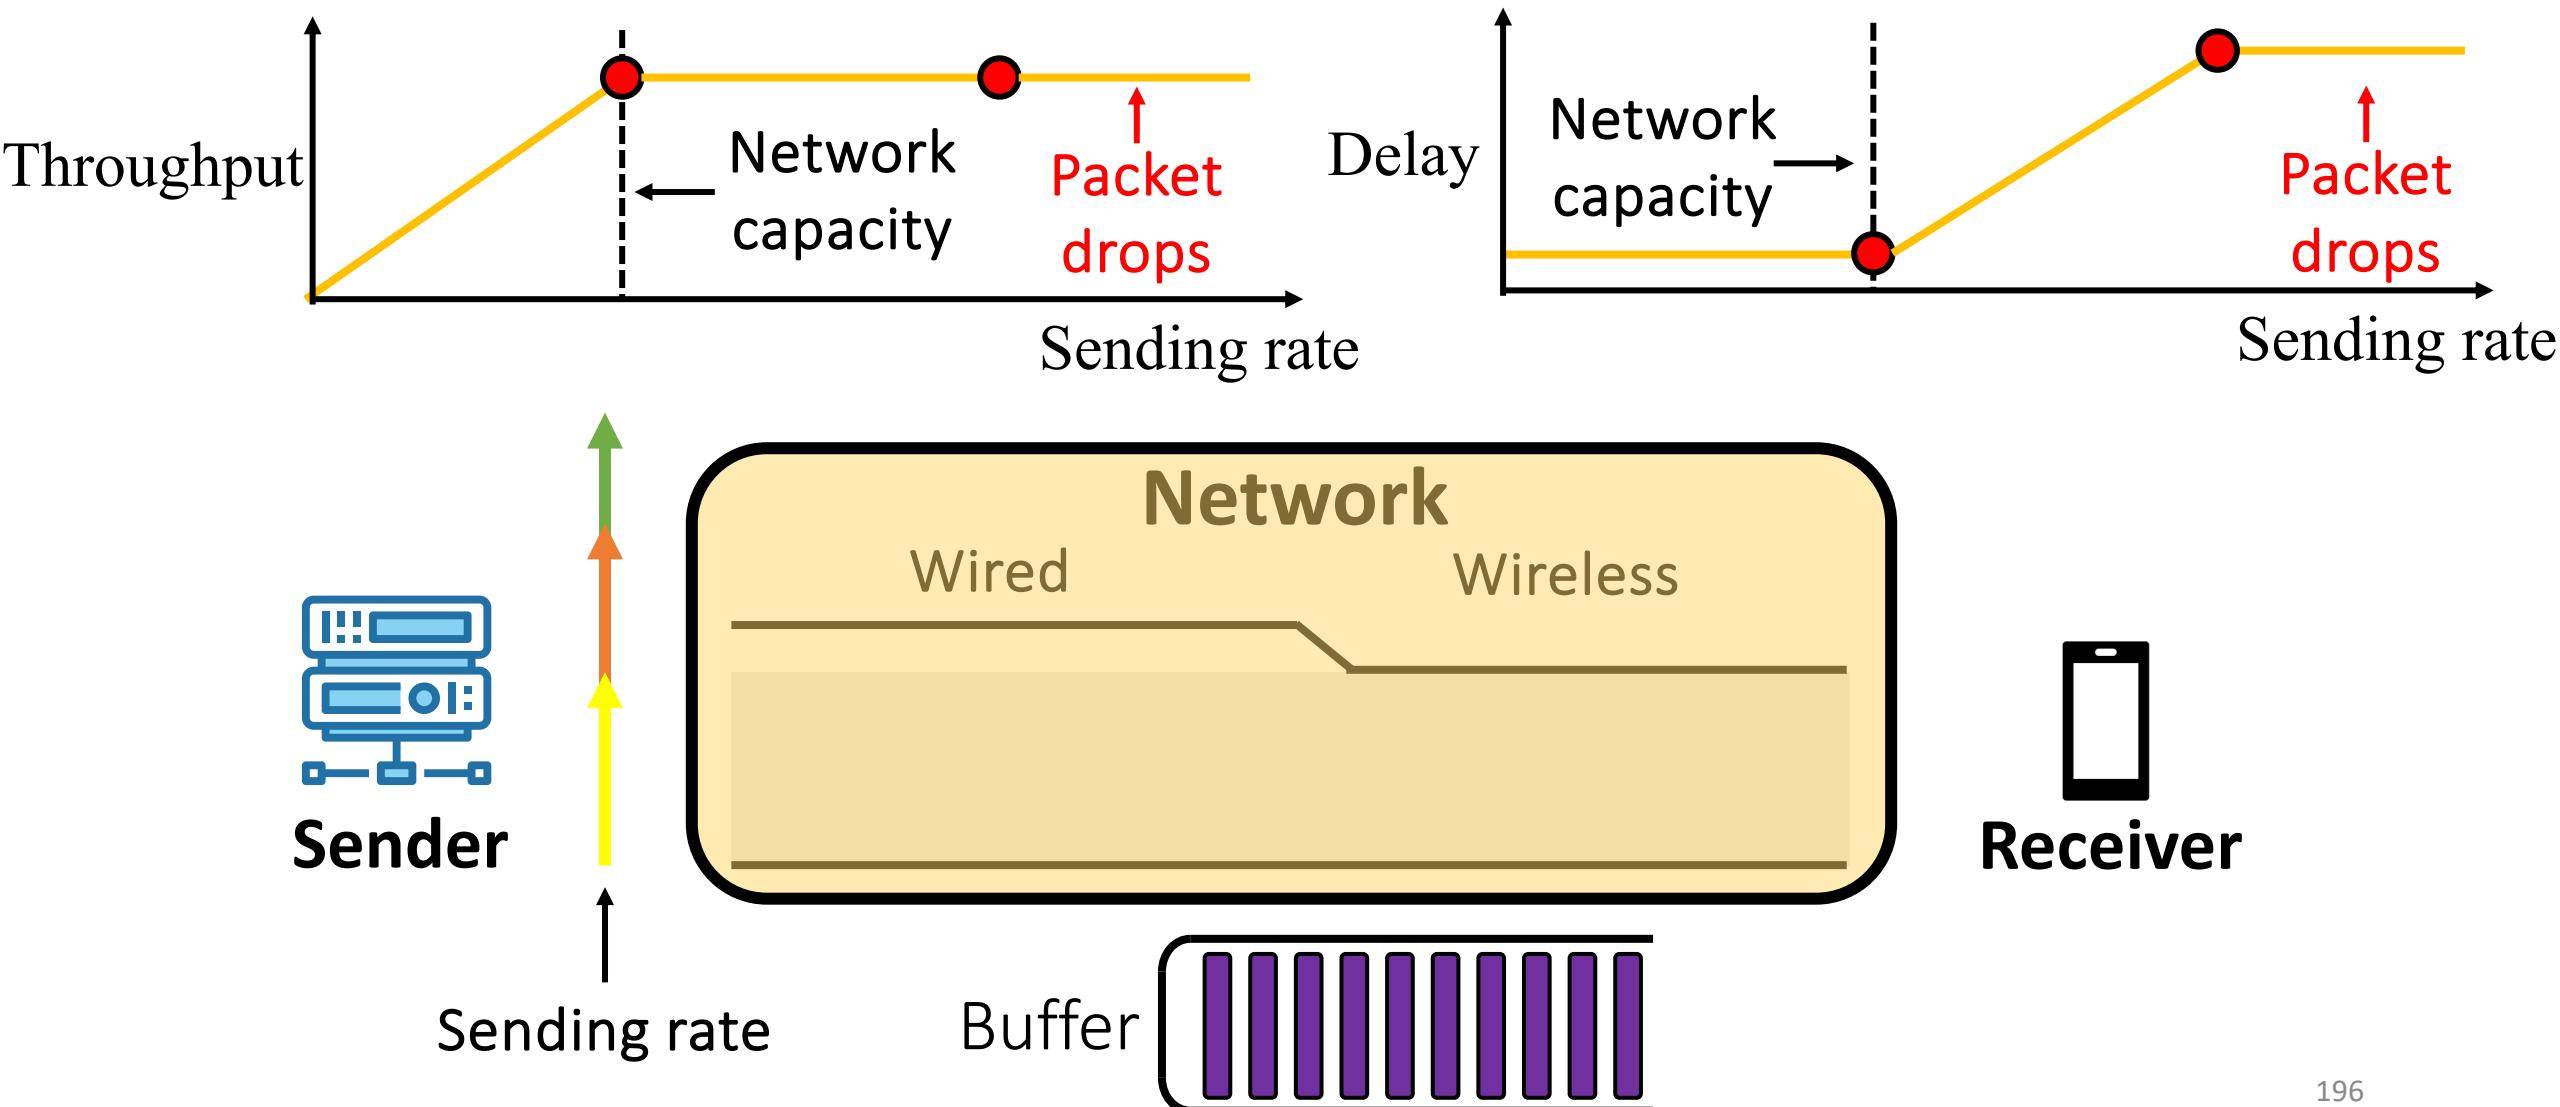

- TCP (classic, CUBIC) increase TCP's sending rate until packet loss occurs at some router's output: the *bottleneck link*
- understanding congestion: useful to focus on congested bottleneck link

## Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

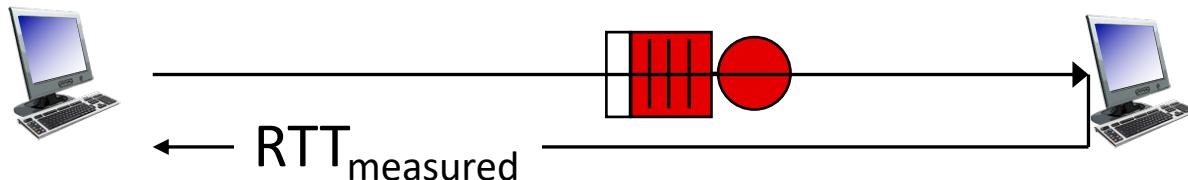

## Type 2: Pure end-to-end solution without cooperation from the network: probing for the capacity

# Delay-based TCP congestion control

Keeping sender-to-receiver pipe “just full enough, but no fuller”: keep bottleneck link busy transmitting, but avoid high delays/buffering

$$\text{measured throughput} = \frac{\text{\# bytes sent in last RTT interval}}{\text{RTT}_{\text{measured}}}$$

## Delay-based approach:

- $\text{RTT}_{\min}$  - minimum observed RTT (uncongested path)
- uncongested throughput with congestion window  $\text{cwnd}$  is  $\text{cwnd}/\text{RTT}_{\min}$ 
  - if measured throughput “very close” to uncongested throughput  
increase  $\text{cwnd}$  linearly /\* since path not congested \*/
  - else if measured throughput “far below” uncongested throughput  
decrease  $\text{cwnd}$  linearly /\* since path is congested \*/

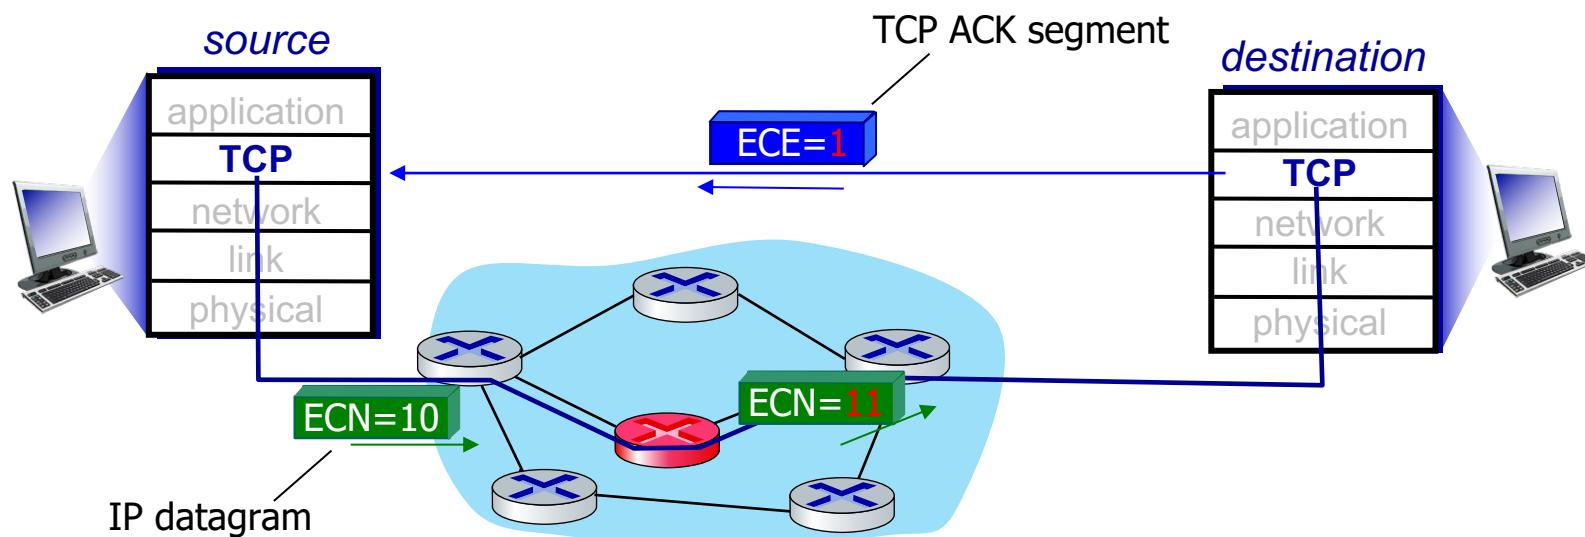

# Delay-based TCP congestion control

- congestion control without inducing/forcing loss
- maximizing throughout (“keeping the just pipe full... ”) while keeping delay low (“...but not fuller”)
- a number of deployed TCPs take a delay-based approach
  - BBR deployed on Google’s (internal) backbone network

# Explicit congestion notification (ECN)

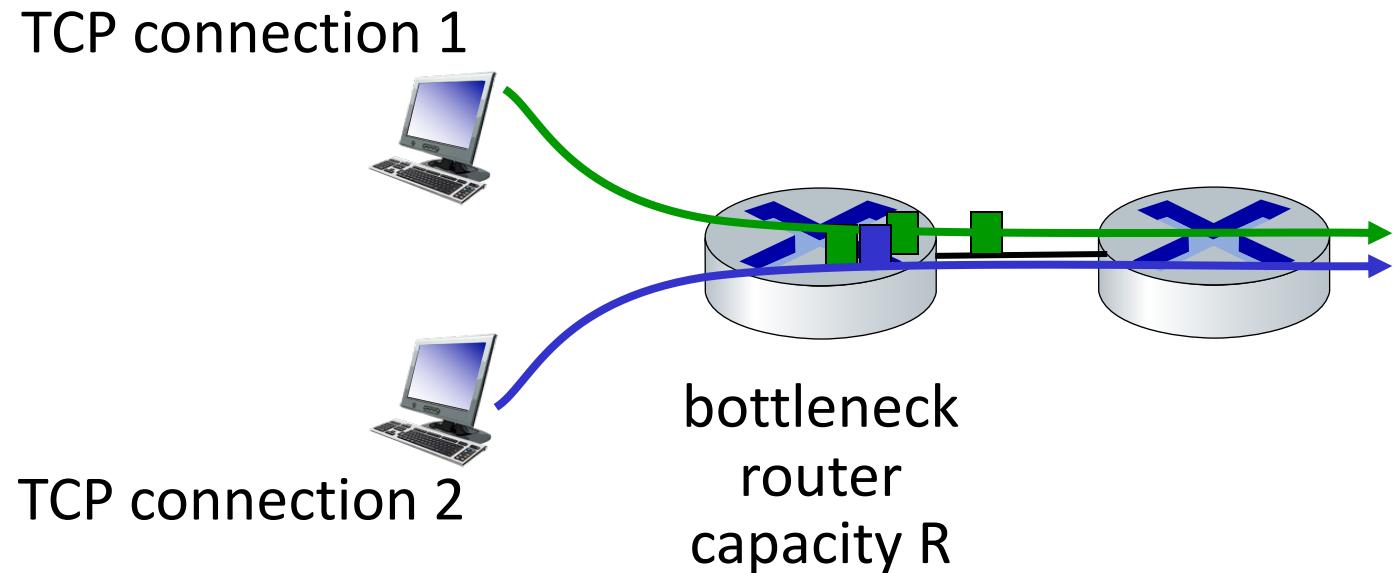

TCP deployments often implement *network-assisted* congestion control:

- two bits in IP header (ToS field) marked *by network router* to indicate congestion
  - *policy* to determine marking chosen by network operator
- congestion indication carried to destination
- destination sets ECE bit on ACK segment to notify sender of congestion
- involves both IP (IP header ECN bit marking) and TCP (TCP header C,E bit marking)

# TCP fairness

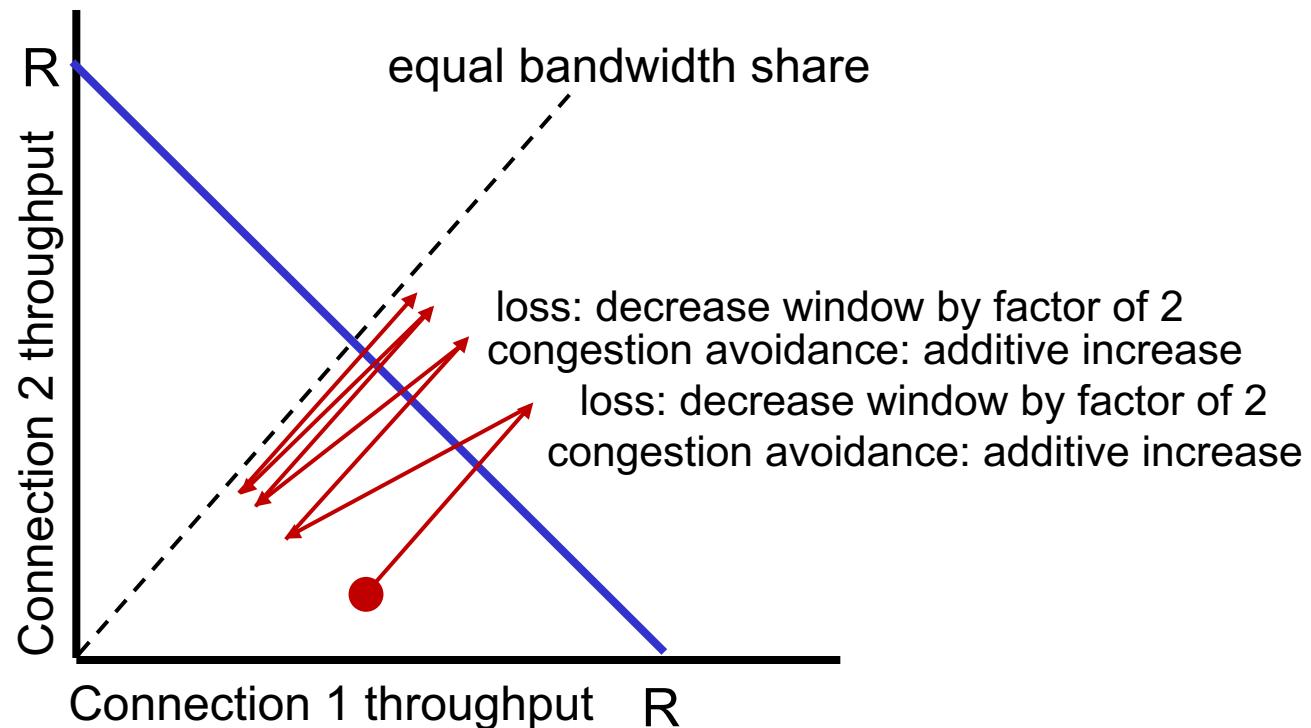

**Fairness goal:** if  $K$  TCP sessions share same bottleneck link of bandwidth  $R$ , each should have average rate of  $R/K$

# Q: is TCP Fair?

Example: two competing TCP sessions:

- additive increase gives slope of 1, as throughout increases
- multiplicative decrease decreases throughput proportionally

*Is TCP fair?*

**A:** Yes, under idealized assumptions:

- same RTT
- fixed number of sessions only in congestion avoidance

# Fairness: must all network apps be “fair”?

## Fairness and UDP

- multimedia apps often do not use TCP
  - do not want rate throttled by congestion control
- instead use UDP:
  - send audio/video at constant rate, tolerate packet loss
- there is no “Internet police” policing use of congestion control

## Fairness, parallel TCP connections

- application can open *multiple* parallel connections between two hosts
- web browsers do this , e.g., link of rate R with 9 existing connections:
  - new app asks for 1 TCP, gets rate R/10
  - new app asks for 11 TCPs, gets R/2

# Transport layer: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

# Evolving transport-layer functionality

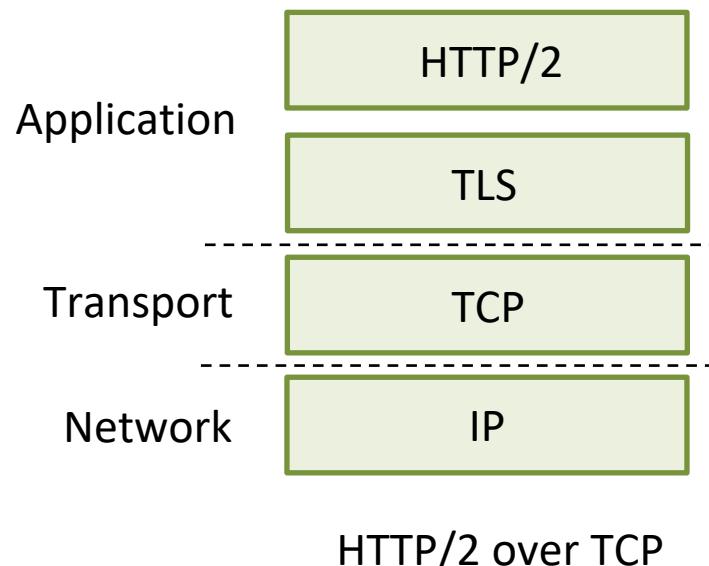

- TCP, UDP: principal transport protocols for 40 years
- different “flavors” of TCP developed, for specific scenarios:

Scenario	Challenges
Long, fat pipes (large data transfers)	Many packets “in flight”; loss shuts down pipeline
Wireless networks	Loss due to noisy wireless links, mobility; TCP treat this as congestion loss
Long-delay links	Extremely long RTTs
Data center networks	Latency sensitive
Background traffic flows	Low priority, “background” TCP flows

- moving transport–layer functions to application layer, on top of UDP
  - HTTP/3: QUIC

# QUIC: Quick UDP Internet Connections

- application-layer protocol, on top of UDP
  - increase performance of HTTP
  - deployed on many Google servers, apps (Chrome, mobile YouTube app)

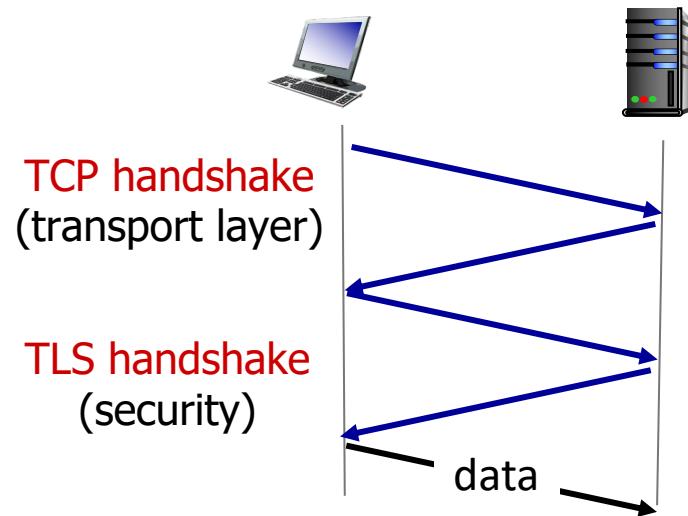

# QUIC: Quick UDP Internet Connections

adopts approaches we've studied in this chapter for connection establishment, error control, congestion control

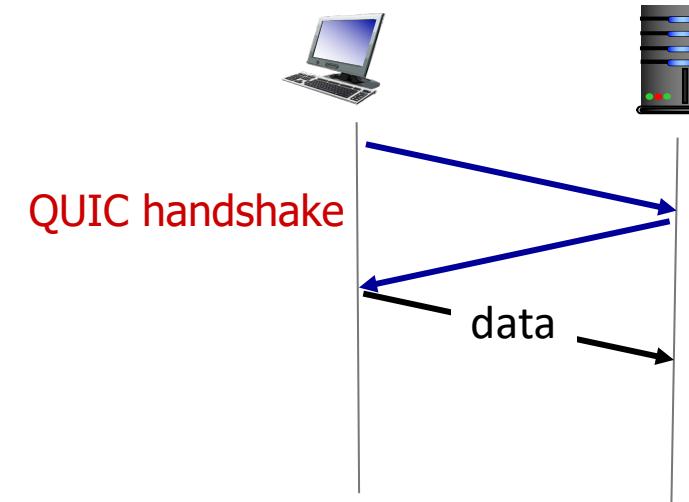

- **error and congestion control:** “Readers familiar with TCP’s loss detection and congestion control will find algorithms here that parallel well-known TCP ones.” [from QUIC specification]
- **connection establishment:** reliability, congestion control, authentication, encryption, state established in one RTT
- multiple application-level “streams” multiplexed over single QUIC connection
  - separate reliable data transfer, security
  - common congestion control

# QUIC: Connection establishment

TCP (reliability, congestion control state) + TLS (authentication, crypto state)

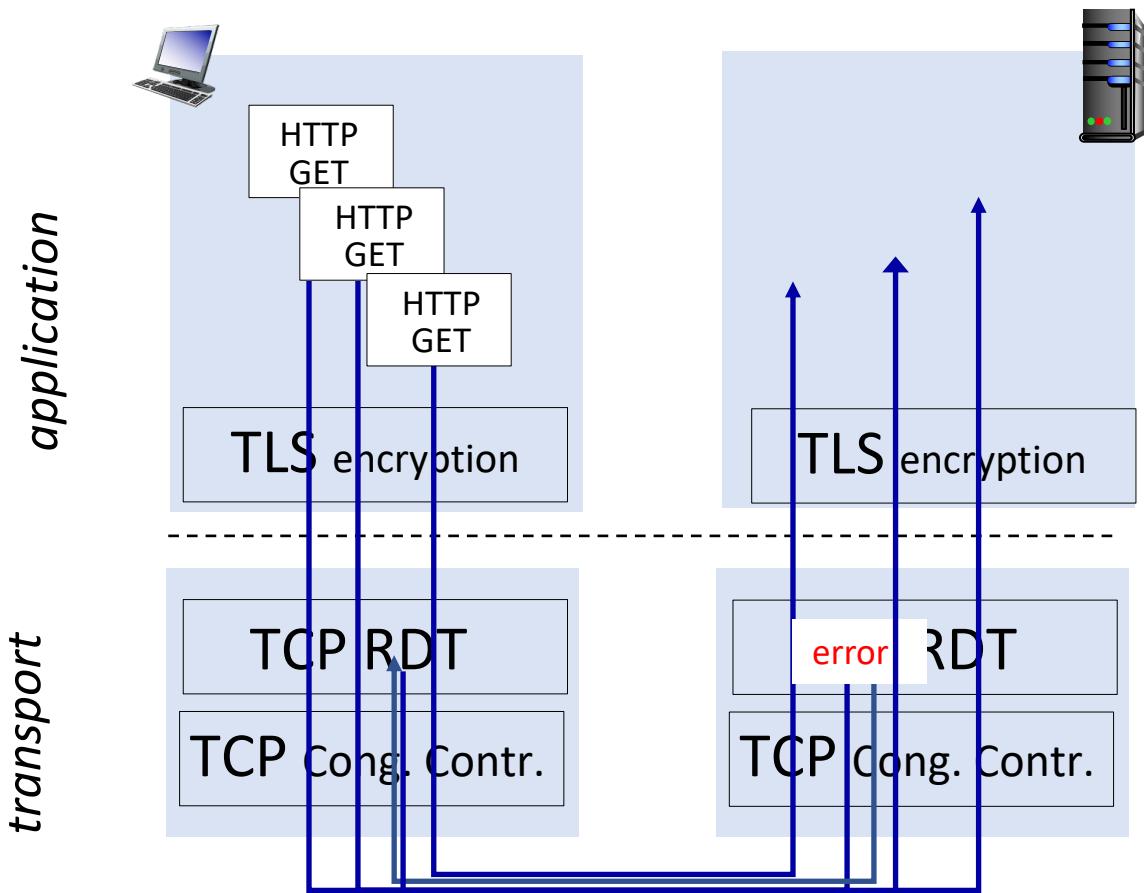

- 2 serial handshakes

QUIC: reliability, congestion control, authentication, crypto state

- 1 handshake

# QUIC: streams: parallelism, no HOL blocking

(a) HTTP 1.1

# Chapter 3: summary

- principles behind transport layer services:
  - multiplexing, demultiplexing
  - reliable data transfer
  - flow control
  - congestion control
- instantiation, implementation in the Internet
  - UDP
  - TCP

## Up next:

- leaving the network “edge” (application, transport layers)
- into the network “core”
- two network-layer chapters:
  - data plane
  - control plane
